Abstract

Recent research on mutual exclusion for shared-memory systems has focused on local spin algorithms. Performance is measured using the remote memory references (RMRs) metric. As common in recent literature, we consider a standard asynchronous shared memory model with \(N\) processes, which allows atomic read, write and compare-and-swap (short: CAS) operations.

In such a model, the asymptotically tight upper and lower bounds on the number of RMRs per passage through the Critical Section is \(\Theta(\log N)\) for the optimal deterministic algorithms \[27, 7\]. Recently, several randomized algorithms have been devised that break the \(\Omega(\log N)\) barrier and need only \(o(\log N)\) RMRs per passage in expectation \[16, 17, 8\]. In this paper we present the first randomized abortable mutual exclusion algorithm that achieves a sub-logarithmic expected RMR complexity. More precisely, against a weak adversary (which can make scheduling decisions based on the entire past history, but not the latest coin-flips of each process) every process needs an expected number of \(O(\log N/\log \log N)\) RMRs to enter and exit the critical section. If a process receives an abort-signal, it can abort an attempt to enter the critical section within a finite number of its own steps and by incurring \(O(\log N/\log \log N)\) RMRs.

1 Introduction

Mutual exclusion, introduced by Dijkstra \[11\], is a fundamental and well studied problem. A mutual exclusion object (or lock) allows processes to synchronize access to a shared resource. Each process obtains a lock through a capture protocol but at any time, at most one process can own the lock. A process is said to own a lock if it participates in a “capture” protocol designed for the object, and completes it. The owner of the lock can access the shared resource, while all other processes wait in their capture protocol for the owner to “release” the lock. The owner of a lock can execute a release protocol which frees up the lock. The capture protocol and release protocol are often denoted entry and exit section, and a process that owns the lock is in the critical section.

In this paper, we consider the standard cache-coherent (CC) shared model with \(N\) processes that supports atomic read, write, and compare-and-swap (short: CAS) operations. In this model, all shared registers are stored in globally accessible shared memory. In addition, each process has a local cache and a cache protocol ensures coherency. A Remote Memory Reference (short: RMR) is a shared memory access of a register that cannot be resolved locally (i.e., a cache miss). Mutual exclusion algorithms require processes to busy-wait, so the traditional step complexity measure, which counts the number of shared memory accesses, is not useful.

Early mutual exclusion locks were designed for uniprocessor systems that supported multitasking and time-sharing. A comprehensive survey of these locking algorithms is presented in [25]. One of the biggest shortcomings of these early locking algorithms is that they did not take into account an important hardware technology trend – the steadily growing gap between high processor speeds and the low speed/bandwidth of the processor-memory interconnect [9]. A memory access that traverses the processor-to-memory interconnect, called a remote memory reference, takes much more time than a local memory access.

Recent research [5, 24, 2, 23, 6, 10, 21, 22] on mutual exclusion algorithms therefore focuses on minimizing the number of remote memory references (RMR). The maximum number of RMRs that any process requires (in any execution) to capture and release a lock is called the RMR complexity of the mutual exclusion algorithm. RMR complexity is the metric used to analyze the efficiency of mutual exclusion algorithms, as opposed to the traditional metric of counting steps taken by a process (step complexity). Step complexity is problematic, since for mutual exclusion algorithms, a process may perform an unbounded number of memory accesses (each considered a step) while busy-waiting for another process to release the lock [1].

Algorithms that perform all busy-waiting by repeatedly reading locally accessible shared variables, achieve bounded RMR complexity and have practical performance benefits [5]. Such algorithms are termed local spin algorithms. A comprehensive survey of these algorithms is presented in [4]. Yang and Anderson presented the first $O(\log N)$ RMRs mutual exclusion algorithm [27] using only reads and writes. Anderson and Kim [2] conjectured that this was optimal, and the conjecture was proved by Attiya, Hendler, and Woelfel [7].

Local spin mutual exclusion locks do not meet a critical demand of many systems [26]. Specifically, the locks employed in database systems and in real time systems must support a “timeout” capability which allows a process that waits “too long” to abort its attempt to acquire the lock. The ability of a thread to abort its lock attempt is crucial in database systems; for instance in Oracle’s Parallel Server and IBM’s DB2, this ability serves the dual purpose of recovering from transaction deadlock and tolerating preemption of the thread that holds the lock [26]. In real time systems, the abort capability can be used to avoid overshooting a deadline. Locks that allow a process to abort its attempt to acquire the lock are called abortable locks. Jayanti presented an efficient deterministic abortable lock [21] with worst-case $O(\log N)$ RMR complexity, which is optimal for deterministic algorithms.

In this paper we present the first randomized abortable mutual exclusion algorithm that achieves a sub-logarithmic RMR complexity. Due to the inherent asynchrony in the system, the RMRs incurred by a process during a lock capture and release depend on how the steps of all the processes in the system were scheduled one after the other. Therefore, the maximum RMRs incurred by any process during any lock attempt are determined by the “worst” schedule that makes some process incur a large number of RMRs. To analyze the RMR complexity of lock algorithms, an adversarial scheduler called the adversary is defined. The lower bound of $\Omega(\log N)$ in [7] for mutual exclusion algorithms that use only reads and writes holds for deterministic algorithms where the adversary knows all processes’ future steps. The lower bound does not hold for randomized algorithms where processes flip coins to determine their next steps. Randomized algorithms limit the power of an adversary since the adversary cannot know the result of future coin flips. Adversaries of varying powers have been defined. The most common ones are the oblivious, the weak, and the adaptive adversary [6]. An oblivious adversary makes all scheduling decisions in advance, before any process flips a coin. This model corresponds to a system, where the coin flips made by processes have no influence on the scheduling. A more realistic model is the weak adversary, who sees the coin flip of a process not before that process has taken a step following that coin flip. The adaptive adversary models the strongest adversary with reasonable powers, and it can see every coin flip as it appears,
and can use that knowledge for any future scheduling decisions. Hendler and Woelfel [16] and later Giakkoupis and Woelfel [12] established a tight bound of $\Theta(\log N / \log \log N)$ expected RMR complexity for randomized mutual exclusion against the adaptive adversary. Recently Bender and Gilbert [8] presented a randomized lock that has amortized $O(\log^2 \log N)$ expected RMR complexity against the oblivious adversary. Unfortunately, this algorithm is not strictly deadlock-free (processes may deadlock with small probability, so deadlock has to be expected in a long execution). Our randomized abortable mutual exclusion algorithm is deadlock-free, works against the weak adversary and achieves the same expected RMR complexity as the algorithm by Hendler and Woelfel, namely $O(\log N / \log \log N)$ expected RMR complexity against the weak adversary.

The randomized algorithm we present uses CAS objects and read-write registers. Golab, Hadzilacos, Hendler, and Woelfel [14] (see also [13]) presented an $O(1)$-RMRs implementation of a CAS object using only read-write registers. Moreover, they proved that one can simulate any deterministic shared memory algorithm that uses reads, writes, and conditional operations (such as CAS operations), with a deterministic algorithm that uses only reads and writes, with only a constant increase in the RMR complexity. Recently in [15], Golab, Higham and Woelfel demonstrated that using linearizable implemented objects in place of atomic objects in randomized algorithms allows the adversary to change the probability distribution of results. Therefore, in order to safely use implemented objects in place of atomic ones in randomized algorithms, it is not enough to simply show that the implemented objects are linearizable. Also in [15], it is proved that there exists no general correctness condition for the weak adversary, and that the weak adversary can gain additional power depending on the linearizable implementation of the object. Therefore, in this paper we assume that CAS operations are atomic.

**Abortable Mutual Exclusion.** We formalize the notion of an abortable lock by specifying two methods, \texttt{lock()} and \texttt{release()}, that processes can use to capture and release the lock, respectively. The model assumes that a process may receive a signal to abort at any time during its \texttt{lock()} call. If that happens, and only then, the process may fail to capture the lock, in which case method \texttt{lock()} returns value $\perp$. Otherwise the process captures the lock, and method \texttt{lock()} returns a non-$\perp$ value, and the \texttt{lock()} call is deemed successful. Note that a \texttt{lock()} call may succeed even if the process receives a signal to abort during a \texttt{lock()} call.

Code executed by a process after a successful \texttt{lock()} method call and before a subsequent \texttt{release()} invocation is defined to be its Critical Section. If a process executes a successful \texttt{lock()} call, then the process’s passage is defined to be the \texttt{lock()} call, and the subsequent Critical Section and \texttt{release()} call, in that order. If a process executes an unsuccessful \texttt{lock()} call, then it does not execute the Critical Section or a \texttt{release()} call, and the process’s passage is just the \texttt{lock()} call. Code executed by a process outside of any passage is defined to be its Remainder Section.

The abort-way is defined to be the steps taken by a process during a passage that begins when the process receives a signal to abort and ends when the process returns to its Remainder Section. Since it makes little sense to have an abort capability where processes have to wait for other processes, the abort-way is required to be bounded wait-free (i.e., processes execute the abort-way in a bounded number of their own steps). This property is known as bounded abort. Other properties are defined as follows. **Mutual Exclusion:** At any time there is at most one process in the Critical Section; **Deadlock Freedom:** If all processes in the system take enough steps, then at least one of them will return from its \texttt{lock()} call; **Starvation Freedom:** If all processes in the system take enough steps, then every process will return from its \texttt{lock()} call. The abortable mutual exclusion problem is to implement an object that provides methods \texttt{lock()} and \texttt{release()} such that it that satisfies mutual exclusion, deadlock freedom, and bounded abort.
1.1 Model

Our model of computation, the asynchronous shared-memory model [20] with $N$ processes which communicate by executing operations on shared objects. Every process executes its program by taking steps, and does not fail. A step is defined to be the execution of all local computations followed by an operation on a shared object. We consider a system that supports atomic read-write registers and CAS() objects.

A read-write register $R$ stores a value from some set and supports two atomic operations $R$.Read() and $R$.Write(). Operation $R$.Read() returns the value of the register and leaves its content unchanged, and operation $R$.Write($v$) writes the value $v$ into the register and returns nothing. A CAS object $O$ stores a value from some set and supports two atomic operations $O$.CAS() and $O$.Read(). Operation $O$.Read() returns the value stored in $O$. Operation $O$.CAS($exp$, new) takes two arguments $exp$ and new and attempts to change the value of $O$ from $exp$ to new. If the value of $O$ equals $exp$ then the operation $O$.CAS($exp$, new) succeeds, and the value of $O$ is changed from $exp$ to new, and true is returned. Otherwise, the operation fails, and the value of $O$ remains unchanged and false is returned.

In addition, a process can execute local coin flip operations that returns an integer value distributed uniformly at random from an arbitrary finite set of integers. The scheduling, generated by the adversary, can depend on the random values generated by the processes. We assume the weak adversary model (see for example [6]) that decides at each point in time the process that takes the next step. In order to make this decision, it can take all preceding events into account, except the results of the most recent coin flips by processes that are yet to execute a shared memory operation after the coin flip.

As mentioned earlier, we consider the cache-coherent (CC) model where each processor has a private cache in which it maintains local copies of shared objects that it accesses. The private cache is logically situated “closer” to the processor than the shared memory, and therefore it can be accessed for free. The shared memory is an external memory accessible to all processors, and is considered remote to all processors. We assume that a hardware protocol ensures cache consistency (i.e., that all copies of the same object in different caches are valid and consistent). A memory access to a shared object that requires access to remote memory is called a remote memory reference (RMR). The RMR complexity of a algorithm is the maximum number of RMRs that a process can incur during any execution of the algorithm.

1.2 Results

We present several building blocks for our algorithm in Section 2. In Sections 3 and 4 we give an overview of the randomized mutual exclusion algorithm. Our results are summarized by the following theorem.

Theorem 1.1. There exists a starvation-free randomized abortable $N$ process lock against the weak adversary, where a process incurs $O(\log N / \log \log N)$ RMRs in expectation per passage. The lock requires $O(N)$ CAS objects and read-write registers

2 Building Blocks

A Randomized CAS Counter. A CAS counter object with parameter $k \in \mathbb{Z}^+$ complements a CAS object by supporting an additional $\text{inc}()$ operation (apart from $\text{CAS}()$ and $\text{Read}()$ operations) that increments the object’s value. The object takes values in $\{0, \ldots, k\}$, and initially the object’s value is 0. Operation $\text{inc}()$ takes no arguments, and if the value of the object is in $\{0, \ldots, k - 1\}$,
then the operation increments the value and returns the previous value. Otherwise, the value of the object is unchanged and the integer \( k \) is returned. We will use such an object for \( k = 2 \) to assign three distinct roles to processes.

Our implementation of the \( \text{inc()} \) operation needs only \( O(1) \) RMRs in expectation. A deterministic implementation of a \( \text{CAS} \) counter for \( k = 2 \) and constant worst-case RMR complexity does not exist: Replacing our randomized \( \text{CAS} \) counter with a deterministic one that has worst-case RMR complexity \( T \) yields a deterministic abortable mutual exclusion algorithm with worst-case RMR complexity \( O(T \cdot \log N / \log \log N) \). From the lower bound for deterministic mutual exclusion by Attiya et al. \cite{Attiya97}, such an algorithm does not exist, unless \( T = \Omega(\log \log N) \).

In Appendix \[A\] we describe a randomized \( \text{CAS} \) counter, called \( \text{RCAScounter}_k \), where the \( \text{inc()} \) method is allowed to fail. The idea is, that to increase the value of the object, a process randomly guesses its current value, \( v \), and then executes a \( \text{CAS}(v, v + 1) \) operation. An adaptive adversary could intervene between the steps involving the random guess and the subsequent \( \text{CAS} \) operation, thereby affecting the failure probability of an \( \text{inc()} \) method call, but a weak adversary cannot do so.

**Lemma 2.1.** Object \( \text{RCAScounter}_k \) is a randomized wait-free linearizable \( \text{CAS} \) Counter, where the probability that an \( \text{inc()} \) method call fails is \( \frac{1}{k+1} \) against the weak adversary. Each of the methods of \( \text{RCAScounter}_k \) has \( O(1) \) step complexity.

**A Single-Fast-Multi-Slow Universal Construction.** A universal construction object provides a linearizable concurrent implementation of any object with a sequential specification that can be given by deterministic code. In Appendix \[B\] we devise a universal construction object \( \text{SFM-UnivConst}(T) \) for \( N \) processes \(^1\) which provides two methods, \( \text{doFast}(op) \) and \( \text{doSlow}(op) \), to perform any operation \( op \) on an object of type \( T \). The idea is that \( \text{doFast()} \) methods cannot be called concurrently, but are executed very fast, i.e., they have \( O(1) \) step complexity. On the other hand, \( \text{doSlow()} \) methods need \( O(N) \) steps. The algorithm is based on a helping mechanism in which \( \text{doSlow()} \) methods help a process that wants to execute a \( \text{doFast()} \) method.

**Lemma 2.2.** Object \( \text{SFM-UnivConst}(T) \) is a wait-free universal construction that implements an object \( O \) of type \( T \), for \( N \) processes, and an operation \( op \) on object \( O \) is performed by executing either method \( \text{doFast}(op) \) or \( \text{doSlow}(op) \), and no two processes execute method \( \text{doFast()} \) concurrently. Methods \( \text{doFast()} \) and \( \text{doSlow()} \) have \( O(1) \) and \( O(N) \) step complexity respectively.

**The Abortable Promotion Array.** An object \( O \) of type \( \text{AbortableProArray}_k \) stores a vector of \( k \) integer pairs. It provides some specialized operations on the vector, such as conditionally adding/removing elements, and earmarking a process (associated with an element of the vector) for some future activity. Initially the value of \( O = (O[0], O[1], \ldots, O[k-1]) \) is \( (\langle 0, \bot \rangle, \ldots, \langle 0, \bot \rangle) \). The object supports operations \( \text{collect()}, \text{abort()}, \text{promote()}, \text{remove()}\) and \( \text{reset()} \) (see Figure \[5\] in the appendix). Operation \( \text{collect}(X) \) takes as argument an array \( X[0 \ldots k-1] \) of integers, and is used to “register” processes into the array. The operation changes \( O[i] \), for all \( i \) in \( \{0, \ldots, k-1\} \), to value \( \langle \text{REG}, X[i] \rangle \) except if \( O[i] \) is \( \langle \text{ABORT}, s \rangle \), for some \( s \in Z \). In the latter case the value of \( O[i] \) is unchanged. Process \( i \) is said to be registered in the array if a \( \text{collect()} \) operation changes \( O[i] \) to value \( \langle \text{REG}, s \rangle \), for some \( s \in Z \). The object also allows processes to “abort” themselves from

\(^1\)For the DSM model, this also follows from a result by Golab, Hadzilacos, Hendler, and Woelfel \cite{Golab91}. They established a super-constant lower bound on the RMR complexity of a deterministic bounded counter that can count up to two, and also supports a reset operation.

\(^2\)We use the universal construction object for smaller sets of processes, specifically for sets of size \( O(\log N / \log \log N) \).
the array using the operation \texttt{abort()}. Operation \texttt{abort}(i, s) takes as argument the integers \(i\) and \(s\), where \(i \in \{0, \ldots, k - 1\}\) and \(s \in \mathbb{Z}\). The operation changes \(O[i]\) to value \langle \text{ABORT}, s \rangle\) and returns \texttt{true}, only if \(O[i]\) is not equal to \langle \text{PRO}, s' \rangle\), for some \(s' \in \mathbb{Z}\). Otherwise the operation returns \texttt{false}. Process \(i\) aborts from the array if it executes an \texttt{abort}(i, s) operation that returns \texttt{true}. A registered process in the array that has not aborted can be “promoted” using the \texttt{promote()} operation. Operation \texttt{promote()} takes no arguments, and changes the value of the element in \(O\) with the smallest index and that has value \langle \text{REG}, s \rangle\), for some \(s \in \mathbb{Z}\), to value \langle \text{PRO}, s \rangle\), and returns \langle \text{i, s} \rangle\), where \(i\) is the index of that element. If there exists no element in \(O\) with value \langle \text{REG}, s \rangle\), for some \(s \in \mathbb{Z}\), then \(O\) is unchanged and the value \langle \perp, \perp \rangle\) is returned. Process \(i\) is promoted if a \texttt{promote()} operation returns \langle \text{i, s} \rangle\), for some \(s \in \mathbb{Z}\). Operation \texttt{reset()} resets the entire array to its initial state.

Note that an aborted process in the array, cannot be registered into the array or be promoted, until the array is reset. If a process tries to abort itself from the array but finds that it has already been promoted, then the abort fails. This ensures that a promoted process takes responsibility for some activity that other processes expect of it.

In the context of our abortable lock, the \(i\)-th element of the array stores the current state of process with ID \(i\), and a sequence number associated with the state. Operation \texttt{collect()} is used to register a set of participating processes into the array. Operation \texttt{abort}(i, s) is executed only by process \(i\), to abort from the array. Operation \texttt{promote()} is used to promote an unaborted registered process from the array, so that the promoted process can fulfill some future obligation.

In our abortable lock of Section 3 we need a wait-free linearizable implementation of type \texttt{AbortableProArray}\(_\Delta\), where \(\Delta\) is the maximum number of processes that can access the object concurrently, and we achieve this by using object \texttt{SFMSUnivConst(AbsrutableProArray}\(_\Delta\)). We ensure that no two processes execute operations \texttt{collect()}, \texttt{promote()}, \texttt{reset()} or \texttt{remove()} concurrently, and therefore by we get \(O(1)\) step complexity for these operations by using method \texttt{doFast()}. Operation \texttt{abort()} has \(O(\Delta)\) step complexity since it is performed using method \texttt{doSlow()}, which allows processes to call \texttt{abort()} concurrently.

### 3 The Tree Based Abortable Lock

Our abortable lock algorithm is based on an arbitration tree with branching factor approximately \(\Theta(\log N/\log \log N)\). For convenience we assume (w.l.o.g.) that \(N = \Delta^\Delta - 1\) for some positive integer \(\Delta\), where \(N\) is the maximum number of processes in the system. Then it follows that \(\Delta = \Theta(\log N/\log \log N)\).

As in the algorithm by Hendler and Woelfel [16], we consider a tree with \(N\) leafs and where each non-leaf node has \(\Delta\) children. Every non-leaf node is associated with a lock. Each process is assigned a unique leaf in the tree and climbs up the tree by capturing the locks on nodes on its path until it has captured the lock at the root. Once a process locks the root, it can enter the Critical Section.

The main difficulty is that of designing the locks associated with the nodes of the tree. A simple \texttt{CAS} object together with an “announce array” as used in [16] does not work. Suppose a process \(p\) captures locks of several nodes on its path up to the root and aborts before capturing the root lock. Then it must release all captured node locks and therefore these lock releases cause other processes, which are busy-waiting on these nodes, to incur RMRs. So we need a mechanism to guarantee some progress to these processes, while we also need a mechanism that allows busy-waiting processes to abort their attempts to capture node locks. In [16] progress is achieved as follows: A process \(p\), before releasing a lock on its path, searches(with a random procedure) for other processes that are
To ensure that waiting processes make some progress, we desire that $p$ “collect” busy-waiting processes (if any) at a node into an instance of an object of type $\text{AbortableProArray}_\Delta$, $\text{PawnSet}$, using the operation $\text{collect}()$. Once busy-waiting processes are collected into $\text{PawnSet}$, $p$ can identify a busy-waiting process, if present, using the $\text{PawnSet.promote}()$ operation, while busy-waiting processes themselves can abort using the $\text{PawnSet.abort}()$ operation. Note that $p$ may have to read $O(\Delta)$ registers just to find a single busy-waiting process at a node, where $\Delta$ is the branching factor of the arbitration tree. This is problematic since our goal is to bound the number of steps during a passage to $O(\Delta)$ steps, and thus a process cannot collect at more than one node. For this reason we desire that $p$ transfer all unreleased node locks that it owns to the first busy-waiting process it can find, and then it would be done. And if there are no busy-waiting processes at a node, then $p$ should somehow be able to release the node lock in $O(1)$ steps. Since there are at most $\Delta$ nodes on a path to the root node, $p$ can continue to release captured node locks where there are no busy-waiting processes, and thus not incur more than $O(\Delta)$ overall. We use an instance of $\text{RCAScounter}_2$, $\text{Ctr}$, to help decide if there are any busy-waiting processes at a node lock. Initially, $\text{Ctr}$ is 0, and processes attempt to increase $\text{Ctr}$ using the $\text{Ctr.inc}()$ operation after having registered at the node. Process $p$ attempts to release a node lock by first executing a $\text{Ctr.CAS}(1,0)$ operation. If the operation fails then some process $q$ must have further increased $\text{Ctr}$ from 1 to 2, and thus $p$ can transfer all unreleased locks to $q$, if $q$ has not aborted itself. If $q$ has aborted, then $q$ can perform the collect at the node lock for $p$, since $q$ can afford to incur an additional one-time expense of $O(\Delta)$ RMRs. If $q$ has not aborted then $p$ can transfer its captured locks to $q$ in $O(1)$ steps, and thus making sure some process makes progress towards capturing the root lock. We encapsulate these mechanisms in a randomized abortable lock object, $\text{ALockArray}_\Delta$.

More generally, we specify an object $\text{ALockArray}_n$ for an arbitrary parameter $n < N$. Object $\text{ALockArray}_n$ provides methods $\text{lock}()$ and $\text{release}()$ that can be accessed by at most $n + 1$ processes concurrently. The object is an abortable lock, but with an RMR complexity of $O(n)$ for the abort-way, and constant RMR complexity for $\text{lock}()$. The $\text{release}()$ method is special. If it detects contention (i.e., other processes are busy-waiting), then it takes $O(n)$ RMRs, but helps those other processes to make progress. Otherwise, it takes only $O(1)$ RMRs. Each non-leaf node $u$ in our arbitration tree will be associated with a lock $\text{ALockArray}_\Delta$ and can only be accessed concurrently by the processes owning locks associated with the children of $u$ and one other process.

Method $\text{lock}()$ takes a single argument, which we will call pseudo-ID, with value in $\{0, \ldots, n - 1\}$. We denote a $\text{lock}()$ method call with argument $i$ as $\text{lock}_i()$, but refer to $\text{lock}_i()$ as $\text{lock}()$ whenever the context of the discussion is not concerned with the value of $i$. Method $\text{lock}()$ returns a non-$\bot$ value if a process captures the lock, otherwise it returns a $\bot$ value to indicate a failed $\text{lock}()$ call. A $\text{lock}()$ by process $p$ can fail only if $p$ aborts during the method call. Method $\text{release}()$ takes two arguments, a pseudo-ID $i \in \{0, \ldots, n - 1\}$ and an integer $j$. Method $\text{release}_i(j)$ returns $\text{true}$ if and only if there exists a concurrent call to $\text{lock}()$ that eventually returns $j$. Otherwise method $\text{release}_i(j)$ returns $\text{false}$. The information contained in argument $j$ determines the transferred node locks. Process pseudo-IDs are passed as arguments to the methods to allow the ability for a process to “transfer” the responsibility of releasing the lock to another process. Specifically, we desire that if a process $p$ executes a successful $\text{lock}_i()$ call and becomes
the owner of the lock, then \( p \) does not have to release the lock itself, if it can find some process \( q \) to call \( \text{release}_q() \) on its behalf. In Section 4 we implement object \( \text{ALockArray}_n \), and prove its properties in Appendix 4.2, and thus we get the following lemma.

**Lemma 3.1.** Object \( \text{ALockArray}_n \) can be implemented against the weak adversary for the CC model with the following properties using only \( O(n) \) CAS objects and read-write registers.

(a) Mutual exclusion, starvation freedom, bounded exit, and bounded abort.

(b) The abort-way has \( O(n) \) RMR complexity.

(c) If a process does not abort during a \( \text{lock}() \) call, then it incurs \( O(1) \) RMRs in expectation during the call, otherwise it incurs \( O(n) \) RMRs in expectation during the call.

(d) If a process' call to \( \text{release}(j) \) returns \( \text{false} \), then it incurs \( O(1) \) RMRs during the call, otherwise it incurs \( O(n) \) RMRs during the call.

**High Level Description of the Abortable Lock.** We use a complete \( \Delta \)-ary tree \( T \) of height \( \Delta \) with \( N \) leaves, called the arbitration tree. The root has height \( \Delta \) and the leaves of the tree have height 0. The \( N \) processes in the system line up as \( \{\text{ALockArray}_n\} \). Each node of our arbitration tree \( T \) is a structure of type \( \text{Node} \) that contains a single instance \( L \) of the abortable randomized lock object \( \text{ALockArray}_\Delta \). This allows processes the ability to abort their attempt at any point in time during their ascent to the root node.

**Lock capture protocol - \( \text{lock}_p() \).** During \( \text{lock}_p() \) a process \( p \) attempts to capture every node on its path \( \text{path}_p \) that it does not own, as long as \( p \) has not received a signal to abort. Process \( p \) attempts to capture a node \( u \) by executing a call to \( u.L.lock() \). If \( p \)'s \( u.L.lock() \) call returns \( \infty \) then \( p \) is said to have captured \( u \), and if the call returns an integer \( j \), then \( p \) is said to have been handed over all nodes from \( u \) to \( v \) on \( \text{path}_p \), where \( h_v = j \). We ensure that \( j \geq h_u \). Process \( p \) starts to own node \( u \) when \( p \) captures \( u.L \) or when \( p \) is handed over node \( u \) from the previous owner of node \( u \). Process \( p \) can enter its Critical Section when it owns the root node of \( T \). Process \( p \) may receive a signal to abort during a call to \( u.L.lock() \) as a result of which \( p \)'s call to \( u.L.lock() \) returns either \( \perp \) or a non-\( \perp \) value. In either case, \( p \) then calls \( \text{release}_p() \) to release all locks of nodes that \( p \) has captured in its passage, and then returns from its \( \text{lock}_p() \) call with value \( \perp \).

**Lock release protocol - \( \text{release}_p() \).** An exiting process \( p \) releases all nodes that it owns during \( \text{release}_p() \). Process \( p \) is said to release node \( u \) if \( p \) releases \( u.L \) (by executing \( u.L.release() \) call), or if \( p \) hands over node \( u \) to some other process. Recall that \( p \) hands over node \( u \) if \( p \) executes a \( v.L.release(j) \) call that returns \( \text{true} \) where \( h_v \leq h_u \leq j \). Let \( s \) be the height of the highest node \( p \) owns. During \( \text{release}_p() \), \( p \) climbs up \( T \) and calls \( u.L.release_p(s) \) at every node \( u \) that it owns, until a call returns \( \text{true} \). If a \( u.L.release_p(s) \) call returns \( \text{false} \) (process \( p \) incurs \( O(1) \) steps), then \( p \) is said to have released lock \( u.L \) (and therefore released node \( u \)), and thus \( p \) continues on its path. If a \( u.L.release_p(s) \) call returns \( \text{true} \) (process \( p \) incurs \( O(\Delta) \) steps), then \( p \) has handed over all remaining nodes that it owns to some process that is executing a concurrent \( u.L.lock() \) call at node \( u \), and thus \( p \) does not release any more nodes.

Notice that our strategy to release node locks is to climb up the tree until all node locks are released or a hand over of remaining locks is made. Climbing up the tree is necessary (as opposed to climbing down) in order to hand over node locks to a process, say \( q \), such that the handed over nodes lie on \( \text{path}_q \).
4 The Array Based Abortable Lock

We specified object $ALockArray_n$ in Section 3 and now we describe and implement it (see Figures 1 and 2). Let $L$ be an instance of object $ALockArray_n$.

Registering and Roles at lock $L$. At the beginning of a $\text{lock()}$ call processes register themselves in the apply array by swapping the value REG atomically into their designated slots ($\text{apply}[i]$ for process with pseudo-ID $i$) using a CAS operation. The array apply of $n$ CAS objects is used by processes to register and “deregister” themselves from lock $L$, and to notify each other of certain events at lock $L$.

On registering in the apply array, processes attempt to increase $\text{Ctr}$, an instance of $\text{RCAScounter}_2$, using operation $\text{Ctr}.\text{inc()}$. Recall that $\text{RCAScounter}_2$ is a bounded counter, initially 0, and returns values in $\{0, 1, 2\}$ (see Section 2). Each of these values corresponds to a role at lock $L$. There are four roles that a process can assume during its passage of lock $L$, namely king, queen, pawn and promoted pawn, and a role defines the protocol a process follows during a passage. During an execution, $\text{Ctr}$ cycles from its initial value 0 to non-0 values and then back to 0, multiple times, and we refer to each such cycle as a $\text{Ctr}$-cycle. The process that increases $\text{Ctr}$ from 0 to 1 becomes the king. The process that increases $\text{Ctr}$ from 1 to 2 becomes the queen. All processes that attempt to increase $\text{Ctr}$ any further, are returned value 2 (by specification of object $\text{RCAScounter}_2$), and they assume the role of a pawn process. A pawn process busy-waits until it gets “promoted” at lock $L$ (a process is said to be promoted at lock $L$ if it is promoted in $\text{PawnSet}$), or until it sees the $\text{Ctr}$ value decrease, so that it can attempt to increase $\text{Ctr}$ again. We ensure that a pawn process repeats an attempt to increase $\text{Ctr}$ at most once, before getting promoted. We ensure that at any point in time during the execution, the number of processes that have assumed the role of a king, queen and promoted pawn at lock $L$, respectively, is at most one, and thus we refer to them as $\text{king}_L$, $\text{queen}_L$ and $\text{ppawn}_L$, respectively. We describe the protocol associated with each of the roles in more detail shortly. An array Role of $n$ read-write registers is used by processes to record their role at lock $L$.

Busy-waiting in lock $L$. The king process, $\text{king}_L$, becomes the first owner of lock $L$ during the current $\text{Ctr}$-cycle, and can proceed to enter its Critical Section, and thus it does not busy-wait during $\text{lock()}$. The queen process, $\text{queen}_L$, must wait for $\text{king}_L$ for a notification of its turn to own lock $L$. Then $\text{queen}_L$ spins on $\text{CAS}$ object $\text{Sync}_1$, waiting for $\text{king}_L$ to CAS some integer value into $\text{Sync}_1$. Process $\text{king}_L$ attempts to CAS an integer $j$ into $\text{Sync}_1$ only during its call to $\text{release}(j)$, after it has executed its Critical Section. The pawn processes wait on their individual slots of the apply array for a notification of their promotion.

A collect action at lock $L$. A collect action is conducted by either $\text{king}_L$ during a call to $\text{release()}$, or by $\text{queen}_L$ during a call to $\text{abort()}$. A collect action is defined as the sequence of steps executed by a process during a call to $\text{doCollect()}$. During a call to $\text{doCollect()}$, the collecting process (say $q$) iterates over the array apply reading every slot, and then creates a local array $A$ from the values read and stores the contents of $A$ in the $\text{PawnSet}$ object in using the operation $\text{PawnSet.collect(A)}$. A key point to note is that operation $\text{PawnSet.collect(A)}$ does not overwrite an aborted process’s value in $\text{PawnSet}$ (a process aborts itself in $\text{PawnSet}$ by executing a successful $\text{PawnSet.abort()}$ operation).

A promote action at lock $L$. Operation $\text{PawnSet.promote()}$ during a call to method $\text{doPromote()}$ is defined as a promote action. The operation returns the pseudo-ID of a process that was collected during a collect action, and has not yet aborted from $\text{PawnSet}$. A promote action is conducted at lock $L$ either by $\text{king}_L$, $\text{queen}_L$ or $\text{ppawn}_L$.

Lock handover from $\text{king}_L$ to $\text{queen}_L$. As mentioned, process $\text{queen}_L$ waits for $\text{king}_L$ to finish its Critical Section and then call $\text{release}(j)$. During $\text{king}_L$’s $\text{release}(j)$ call, $\text{king}_L$ attempts to swap integer $j$ into $\text{CAS}$ object $\text{Sync}_1$, that only $\text{king}_L$ and $\text{queen}_L$ access. If $\text{queen}_L$ has not

Figure 1: Implementation of Object ALockArrayₙ
“aborted”, then king\(_L\) successfully swaps \(j\) into Sync\(_1\), and this serves as a notification to queen\(_L\) that king\(_L\) has completed its Critical Section, and that queen\(_L\) may now proceed to enter its Critical Section.

**Aborting an attempt at lock \(L\) by queen\(_L\).** On receiving a signal to abort, queen\(_L\) abandons its lock() call and executes a call to abort() instead. queen\(_L\) first changes the value of its slot in the apply array from REG to PRO, to prevent itself from getting collected in future collects. Since king\(_L\) and queen\(_L\) are the first two processes at \(L\), king\(_L\) will eventually try to handover \(L\) to queen\(_L\). To prevent king\(_L\) from handing over lock \(L\) to queen\(_L\), queen\(_L\) attempts to swap a special value \(\infty\) into Sync\(_1\) in one atomic step. If queen\(_L\) fails then this implies that king\(_L\) has already handed over \(L\) to queen\(_L\), and thus queen\(_L\) returns from its call to abort() with the value written to Sync\(_1\) by king\(_L\), and becomes the owner of \(L\). If queen\(_L\) succeeds then queen\(_L\) is said to have successfully aborted, and thus king\(_L\) will eventually fail to hand over lock \(L\). Since queen\(_L\) has aborted, queen\(_L\) now takes on the responsibility of collecting all registered processes in lock \(L\), and storing them into the PawnSet object. After performing a collect, queen\(_L\) then synchronizes with king\(_L\) again, to perform a promote, where one of the collected processes is promoted. After that, queen\(_L\) deregisters from the apply array by resetting its slot to the initial value \(\langle \bot, \bot\rangle\).

**Aborting an attempt at lock \(L\) by a pawn process.** On receiving a signal to abort a pawn process (say \(p\)) busy-waiting in lock \(L\), abandons its lock() call and executes a call to abort() instead. Process \(p\) first changes the value of its slot in the apply array from REG to PRO, to prevent itself from getting collected in future collects. It then attempts to abort itself in PawnSet by executing the operation PawnSet.abort(\(p\)). If \(p\)'s attempt is unsuccessful then it implies that \(p\) has already been promoted in PawnSet, and thus \(p\) can assume the role of a promoted pawn, and become the owner of \(L\). In this case, \(p\) returns from its abort() call with value \(\infty\) and becomes the owner of \(L\). If \(p\)'s attempt is successful then \(p\) cannot be collected or promoted in future collects and promotion events. In this case, \(p\) deregisters from the apply array by resetting its slot to the

initial value $⟨\bot, \bot⟩$, and returns $\bot$ from its call to abort().

**Releasing lock $L$.** Releasing lock $L$ can be thought of as a group effort between the king$_L$, queen$_L$ (if present at all), and the promoted pawns (if present at all). To completely release lock $L$, the owner of $L$ needs to reset Ctr back to 0 for the next Ctr-cycle to begin. However, the owner also has an obligation to hand over lock $L$ to the next process waiting in line for lock $L$. We now discuss the individual strategies of releasing lock $L$, by king$_L$, queen$_L$ and the promoted processes. To release lock $L$, the owner of $L$ executes a call to release$(j)$, for some integer $j$.

**Synchronizing the release of lock $L$ by king$_L$ and queen$_L$.** Process king$_L$ first attempts to decrease Ctr from 1 to 0 using a CAS operation. If it is successful, then king$_L$ was able to end the Ctr-cycle before any process could increase Ctr from 1 to 2. Thus, there was no queen$_L$ process or pawn processes waiting for their turn to own lock $L$, during that Ctr-cycle. Then king$_L$ is said to have released lock $L$. If king$_L$’s attempt to decrease Ctr from 1 to 0 fails, then king$_L$ knows that there exists a queen$_L$ process that increased Ctr from 1 to 2. Since queen$_L$ is allowed to abort, releasing lock $L$ is not as straightforward as raising a flag to be read by queen$_L$. Therefore, king$_L$ attempts to synchronize with queen$_L$ by swapping the integer $j$ into the object Sync1 using a Sync1.CAS($⟨\bot, j⟩$) operation. Recall that queen$_L$ also attempts to swap a special value $∞$ into object Sync1 using a Sync1.CAS($⟨\bot, j⟩$) operation, in order to abort its attempt. Clearly only one of them can succeed. If king$_L$ succeeds, then king$_L$ is said to have successfully handed over lock $L$ to queen$_L$. If king$_L$ fails, then king$_L$ knows that queen$_L$ has aborted and thus king$_L$ then tries to hand over its lock to one of the waiting pawn processes. The procedure to hand over lock $L$ to one of the waiting pawn processes is to execute a collect action followed by a promote action.

The collect action needs to be executed only once during a Ctr-cycle, and thus we let the process (among king$_L$ or queen$_L$) that successfully swaps a value into Sync1, execute the collect action.

If king$_L$ successfully handed over $L$ to queen$_L$, it collects the waiting pawn processes, so that eventually when queen$_L$ is ready to release lock $L$, queen$_L$ can simply execute a promote action. Since there is no guarantee that king$_L$ will finish collecting before queen$_L$ desires to execute a promote action, the processes synchronize among themselves again, to execute the first promote action of the current Ctr-cycle. They both attempt to swap their pseudo-IDs into an empty CAS object Sync2, and therefore only one can succeed. The process that is unsuccessful, resets Sync1 and Sync2 to their initial value $\bot$, and then executes the promote action, where a waiting pawn process is promoted and handed over lock $L$. If no process were collected during the Ctr-cycle, or all collected pawn processes have successfully aborted before the promote action, then the promote action fails, and thus the owner process resets the PawnSet object, and then resets Ctr from 2 to 0 in one atomic step, thus releasing lock $L$, and resetting the Ctr-cycle.

**The release of lock $L$ by ppawn$_L$.** If a process was promoted by king$_L$ or queen$_L$ as described above, then the promoted process is said to be handed over the ownership of $L$, and becomes the first promoted pawn of the Ctr-cycle. Since a collect for this Ctr-cycle has already been executed, process ppawn$_L$ does not execute any more collects, but simply attempts to hand over lock $L$ to the next collected process by executing a promote action. This sort of promotion and handing over of lock $L$ continues until there are no more collected processes to promote, at which point the last promoted pawn resets the PawnSet object, and then resets Ctr from 2 to 0 in one atomic step, thus releasing lock $L$, and resetting the Ctr-cycle.

All owner processes also deregister themselves from lock $L$, by resetting their slot in the apply array to the initial value $⟨\bot, \bot⟩$. This step is the last step of their release$(j)$ calls, and processes return a boolean to indicate whether they successfully wrote integer $j$ into Sync1 during their
release$(j)$ call. Note that only kingL could possibly return true since it is the only process that attempts to do so, during its release$(j)$ call.

## 5 Conclusion

We presented the first randomized abortable lock that achieves sub-logarithmic expected RMR complexity. While the speed-up is only a modest $O(\log \log n)$ factor over the most efficient deterministic abortable mutual exclusion algorithm, our result shows that randomization can help in principle, to improve the efficiency of abortable locks. Unfortunately, our algorithm is quite complicated; it would be nice to find a simpler one. It would also be interesting to find an algorithm with sub-logarithmic RMR complexity that works against the stronger adversary. In the weak adversary model, no non-trivial lower bounds for mutual exclusion are known, but it seems hard to improve upon $O(\log n/\log \log n)$ RMR complexity, even without the abortability property.

As shown by Bender and Gilbert, \cite{BenderGilbert11}, the picture looks different in the oblivious adversary model. However, their algorithm is only lock-free with high probability. It would be interesting to find a mutual exclusion algorithm with $o(\log n/\log \log n)$ RMR complexity against the oblivious adversary that is lock-free with probability one. It would also be interesting to know whether such an algorithm can be made abortable.

A Implementation of Object RCAScounter<sub>k</sub>

The sequential specification of the CAS Counter object is presented in Figure 3 in the form of type CAScounter<sub>k</sub>. The implementation of our randomized CAS counter object, RCAScounter<sub>k</sub> of type CAScounter<sub>k</sub> is presented in Figure 4. A shared CAS object Count is used to store the value of the counter object, and is initialized to 0. The object provides methods inc(), CAS() and Read(), where the inc() method is allowed to fail, in which case the operation does not change the object state, and returns ⊥ to indicate the failure.

Figure 4: Implementation of Object RCAScounter<sub>k</sub>

During the inc() method, a process p first makes a guess at the counter’s current value by rolling a (k + 1)-sided dice (in line 8) that returns a value in {0, . . . , k} uniformly at random, and stores the value in local variable β. If β = k, then p performs a Read() on Count(in line 10) to verify the correctness of its guess. If p’s guess is correct, then it returns k, otherwise it returns ⊥ (in line 14) to indicate a failed inc() method call. If β ∈ {0, . . . , k − 1}, then p performs a Count.CAS(β, β + 1) operation (in line 11) in order to verify the correctness of its guess and to
increment Count in one atomic step. If p’s guess is correct, then the CAS operation succeeds and the inc() method returns the previous value. Otherwise the inc() method returns ⊥ (in line [14]) to indicate a failed inc() method call.

Method Read() simply reads the current value of Count using a Count.Read() operation (line [17]) and returns the result of the operation. Method CAS() takes two integer parameters old, new, and in line [15] performs a safety check, where it checks whether the value of new is in {0, ..., k}. If the safety check fails, then the method simply returns false. Otherwise, it attempts to change the value of Count from old to new using the Count.CAS(old, new) operation (in line [16]) and returns the result of the operation.

A.1 Analysis and Properties of Object RCAScounter

Consider an instance of the RCAScounter object. Let H be an arbitrary history that consists of all method calls on the instance, except failed inc() calls and pending calls that are yet to execute line [10] (Read operation), line [12] (CAS operation), line [16] (CAS operation) or line [17] (Read operation). If a failed inc() is in the history, it can be linearized at an arbitrary point between its invocation and response, as it does not affect the validity of any other operations. Therefore, it suffices to prove that the history without failed inc() operations is linearizable, and then linearizability of the original history follows. The same argument applies to omitting the selected pending method calls. Since the selected pending method calls do not change any shared object, they cannot affect the validity of any other operations.

We define a point pt(u) for every method u in H. Let I(u) be the interval between u’s invocation and response. Let S be the sequential history obtained by ordering the method calls in H according to the points pt(u). To show that RCAScounter is a randomized linearizable implementation of the type CAScounter, we need to show that the sequential history S is valid, i.e., S lies in the specification of type CAScounter object, and that pt(u) lies in I(u). Let C be an object of type CAScounter, and let S_v be the sequential history obtained when the operations of S are executed sequentially on object C in the order as given in S. Clearly, S_v is a valid sequential history in the specification of type CAScounter by construction. Then to show that S is valid, we show that S = S_v.

Lemma A.1. Object RCAScounter is a randomized linearizable implementation of type CAScounter.

Proof. Let A be an instance of the RCAScounter object. Consider an arbitrary history H that consists of all completed method calls on A, except failed inc() calls, and all pending method calls on A that have executed a successful CAS operation. We now define point pt(u) for every method u in H.

If u is a Read() method call then define pt(u) to be the point in time when the Read operation in line [17] is executed.

If u is an inc() method call that returns from line [10] then pt(u) is the point in time of the Read operation in line [10] and if u’s CAS operation in line [12] succeeds then pt(u) is the point in time of the CAS operation in line [12]. By construction, a Read or CAS operation has been executed during every inc() call in H, and no failed inc() calls are in H. Then it follows that we have defined pt(u) for every inc() call u in H.

If u is a CAS() method call that returns from line [15] then pt(u) is any arbitrary point during I(u), and if u returns from line [16] then pt(u) is the point in time of the CAS operation in line [16]. Clearly pt(u) ∈ I(u) for every method u in H.
Let \( u_i \) be the \( i \)-th operation in \( S \) and \( v_j \) be the \( i \)-th operation in \( S_v \). Let \( \text{Count}(u_i)^+ \) denote the value of object \( \text{Count} \) immediately after \( pt(u_i) \), and let \( \mathcal{C}(v_j)^+ \) denote the value of object \( \mathcal{C} \) after operation \( v_j \) in \( S_v \). We assume that \( u_0 \) is a method call that does not change the state of any shared object of instance \( A \) (such as a \( \text{Read}() \) method) and returns the initial value of the object. This assumption can be made without loss of generality, because the removal of a method call that does not change the state of the object from a linearizable history always leaves a history that is also linearizable. The purpose of the assumption is to simplify the base case of our induction hypothesis.

We now prove by induction on integer \( i \), that \( \text{Count}(u_i)^+ = \mathcal{C}(v_{i-1})^+ \), and that the return value of \( u_i \) matches the value returned by \( v_i \), thereby proving \( S = S_v \).

**Basis** \( (i = 0) \) Since initially the value of object \( \text{Count} \) and the value of the atomic \( \text{CAS} \) operation on the object \( \text{Count} \) are 0, it follows from the definition of the method call \( u_0 \), that \( \text{Count}(u_0)^+ = \mathcal{C}(v_0)^+ = 0 \), and the return value of \( u_0 \) matches that of \( v_0 \).

**Induction Step** \( (i > 0) \) From the induction hypothesis, \( \text{Count}(u_{i-1})^+ = \mathcal{C}(v_{i-1})^+ \).

**Case a** - \( u_i \) is an \( \text{inc()} \) method call that executes a successful \( \text{CAS}() \) operation in line \( 12 \). Then \( pt(u_i) \) is when object \( \text{Count} \) is incremented from \( \beta \) to \( \beta + 1 \) by a successful \( \text{Count. CAS}(\beta, \beta + 1) \) operation in line \( 12 \) and thus \( \text{Count}(u_{i-1})^+ = \beta \) holds. Also, \( u_i \) returns \( \beta = \text{Count}(u_{i-1})^+ \). Since \( u_i \) fails the if-condition of line \( 9 \) \( \beta \neq k \) and therefore \( \text{Count}(u_{i-1})^+ = \beta \neq k \) holds. Now consider operation \( v_i \) in \( S_v \). Since \( \mathcal{C}(v_{i-1})^+ = \text{Count}(u_{i-1})^+ \neq k \), the if-condition of line \( 11 \) fails, and the value of the atomic \( \text{CAS} \) counter is incremented in line \( 2 \) and \( \mathcal{C}(v_{i-1})^+ \) returned in line \( 3 \) Hence \( \text{Count}(u_i)^+ = \mathcal{C}(v_i)^+ \) and the return values match.

**Case b** - \( u_i \) is an \( \text{inc()} \) method call that returns from line \( 10 \). Then \( pt(u_i) \) is when the \( \text{Read}() \) operation on the object \( \text{Count} \) is executed in line \( 10 \). Clearly, the value returned by the \( \text{Read}() \) operation on the object \( \text{Count} \) at \( pt(u_i) \) is \( \text{Count}(u_{i-1})^+ \). Since the if-condition of line \( 10 \) is satisfied, \( \text{Count}(u_{i-1})^+ = k \) and \( u_i \) returns integer \( k \) without changing object \( \text{Count} \). Now consider operation \( v_i \) in \( S_v \). Since \( \mathcal{C}(v_{i-1})^+ = \text{Count}(u_{i-1})^+ \) and \( \text{Count}(u_{i-1})^+ = k \), the if-condition of line \( 11 \) is satisfied and integer \( k \) is returned without changing the atomic \( \text{CAS} \) counter object. Hence \( \text{Count}(u_i)^+ = \mathcal{C}(v_i)^+ \) and the return values match.

**Case c** - \( u_i \) is a \( \text{CAS}() \) method call that returns from line \( 15 \). Then the if-condition of line \( 15 \) is satisfied and thus \( \text{new} \notin \{0, 1, \ldots, k\} \) and \( u_i \) returns \( \text{false} \) without changing \( \text{Count} \). Now consider operation \( v_i \) in \( S_v \). Since \( \text{new} \notin \{0, 1, \ldots, k\} \), the if-condition of line \( 11 \) will be satisfied and the Boolean value \( \text{false} \) is returned without changing the value of object \( \mathcal{C} \). Hence \( \text{Count}(u_i)^+ = \mathcal{C}(v_i)^+ \) and the return values match.

**Case d** - \( u_i \) is a \( \text{CAS}() \) method call that returns from line \( 16 \). Then \( pt(u_i) \) is when the \( \text{CAS} \) operation on the object \( \text{Count} \) is executed in line \( 16 \) and \( u_i \) returns the result of this \( \text{CAS} \) operation. The \( \text{CAS} \) operation attempts to change the value of \( \text{Count} \) from \( \text{old} \) to \( \text{new} \), therefore if \( \text{Count}(u_{i-1})^+ = \text{old} \) then \( \text{Count}(u_i)^+ = \text{new} \) and \( u_i \) returns \( \text{true} \), or else \( \text{Count} \) remains unchanged and \( u_i \) returns \( \text{false} \). Now consider operation \( v_i \) in \( S_v \). From the code structure, if \( \mathcal{C}(v_{i-1})^+ = \text{old} \) then \( \mathcal{C}(v_i)^+ = \text{new} \) and the Boolean value \( \text{true} \) is returned. And if \( \mathcal{C}(v_{i-1})^+ \neq \text{old} \) then the value of object \( \mathcal{C} \) remains unchanged and the Boolean value \( \text{false} \) is returned. Hence \( \text{Count}(u_i)^+ = \mathcal{C}(v_i)^+ \) and the return values match.

**Lemma A.2.** The probability that an \( \text{inc()} \) method call returns \( \bot \) is \( k/(k+1) \) against the weak adversary.

**Proof.** Let the process calling the \( \text{inc()} \) method call (say \( u \)) be \( p \) and let the value of the object \( \text{Count} \) immediately before \( p \) executes line \( 8 \) be \( z \). Since the adversary is weak, no other process executes a shared memory operation after \( p \) chooses \( \beta \) in line \( 8 \) and before \( p \) finishes executing its
next shared memory operation. From the code structure, \( p \) returns \( \perp \) during \( u \) (in line \( 14 \)) if and only if \( z \neq \beta \). Since

\[
\text{Prob}(z \neq \beta) = 1 - \text{Prob}(z = \beta) = 1 - \frac{1}{k+1} = \frac{k}{k+1},
\]

the claim follows.

The following claim follows immediately from an inspection of the code.

Lemma A.3. Each of the methods of \( \text{RCAScounter}_k \) has step complexity \( \O(1) \), and is wait-free.

Lemma 2.1 follows from Lemmas A.1 A.2 and A.3.

### B Specification of Type \( \text{AbortableProArray}_k \)

Type \( \text{AbortableProArray}_k \) is presented in Figure 5.

#### Type \( \text{AbortableProArray}_k \)

\( A: \text{array} [0 \ldots k-1] \) of int pairs \text{init} all \((\perp, \perp)\); \( \text{REG, PRO, ABORT: int init 1, 2, 3} \)

#### Operation \text{collect}(\text{int}[\] \( X \))

1. \text{for } i \leftarrow 0 \text{ to } k-1 \text{ do}
2. \quad \langle v, s \rangle \leftarrow A[i]
3. \quad \text{if } v \neq \text{ABORT } \land X[i] \neq \perp \text{ then } A[i] \leftarrow \langle \text{REG, } X[i] \rangle
4. \text{end}

#### Operation \text{abort}(\text{int } i, \text{ int seq})

5. \langle v, s \rangle \leftarrow A[i]
6. \text{if } v = \text{PRO then } \text{return false}
7. \quad A[i] \leftarrow \langle \text{ABORT, seq} \rangle
8. \quad \text{return true}

#### Operation \text{reset}()

9. \text{for } i \leftarrow 0 \text{ to } k-1 \text{ do } \quad A[i] \leftarrow (0, \perp)

#### Operation \text{promote}()

10. \text{for } i \leftarrow 0 \text{ to } k-1 \text{ do}
11. \quad \langle v, s \rangle \leftarrow A[i]
12. \quad \text{if } v = \text{REG then}
13. \quad \quad A[i] \leftarrow \langle \text{PRO, s} \rangle
14. \quad \quad \text{return } \langle i, s \rangle
15. \quad \text{end}
16. \quad \text{return } \langle \perp, \perp \rangle

#### Operation \text{remove}(\text{int } i)

18. \langle v, s \rangle \leftarrow A[i]
19. \quad A[i] \leftarrow (\text{ABORT, s})

Figure 5: Sequential Specification of Type \( \text{AbortableProArray}_k \)

### C The Single-Fast-Multi-Slow Universal Construction

In this section, rather than implementing object \( \text{SFMSUnivConst}(T) \), we implement a lock-free universal construction object \( \text{SFMSUnivConstWeak}(T) \), with slightly weaker properties than \( \text{SFMSUnivConst}(T) \). An object implementation is lock-free, if in any infinite history \( H \) where processes
continue to take steps, and \( H \) contains only operations on that object, some operation finishes. Object \( \text{SFMSUnivConstWeak}(T) \) has the same properties as object \( \text{SFMSUnivConst}(T) \) except method \( \text{doFast()} \) is lock-free with unbounded step-complexity.

There is a standard technique called operation combining [18] that can be applied to transform our lock-free object \( \text{SFMSUnivConstWeak}(T) \) to the wait-free object \( \text{SFMSUnivConst}(T) \) with \( O(N) \) step complexity for method \( \text{doFast()} \).

By applying the technique of operation combining we can transform our lock-free universal construction \( \text{SFMSUnivConstWeak}(T) \) into our wait-free object \( \text{SFMSUnivConst}(T) \). We however do not provide a proof of its properties. Doing so would be repeating the same “standard” proof ideas from [18], and would result in increasing the size of the paper without contributing to the main ideas of this paper. We do provide proofs for our lock-free universal construction \( \text{SFMSUnivConstWeak}(T) \), and the proofs illustrate the main idea from this section, i.e., how to achieve a linearizable concurrent implementation with support for a \( \text{doFast()} \) method of \( O(1) \) step complexity. We now present the implementation of object \( \text{SFMSUnivConstWeak}(T) \) (see Figure 6).

| Shared Data. A shared register \( \text{mReg} \) stores a 4-tuple \( (m_0, m_1, m_2, m_3) \). We use the notation \( \text{mReg}[i] \) to refer to the \( (i + 1) \)-th tuple element, \( m_i \), stored in register \( \text{mReg} \). Element \( \text{mReg}[0] \) stores the state of object \( O \). Element \( \text{mReg}[1] \) stores the result of the most recent fast operation performed. Elements \( \text{mReg}[2] \) and \( \text{mReg}[3] \) store counts of the number of fast and slow operations | Shared Data. A shared register \( \text{mReg} \) stores a 4-tuple \( (m_0, m_1, m_2, m_3) \). We use the notation \( \text{mReg}[i] \) to refer to the \( (i + 1) \)-th tuple element, \( m_i \), stored in register \( \text{mReg} \). Element \( \text{mReg}[0] \) stores the state of object \( O \). Element \( \text{mReg}[1] \) stores the result of the most recent fast operation performed. Elements \( \text{mReg}[2] \) and \( \text{mReg}[3] \) store counts of the number of fast and slow operations |

Figure 6: Implementation of Object \( \text{SFMSUnivConstWeak}(T) \).
performed respectively. Initially $mReg[0]$ stores the initial state of $O$, $mReg[1]$ has value $\bot$ and $(mReg[2], mReg[3])$ is $(0, 0)$.

A shared register $fastOp$ is used to announce a fast operation to be performed in a pair $(s_0, s_1)$. Element $fastOp[0]$ stores the complete description of a fast operation to be performed. Element $fastOp[1]$ stores a sequence number indicating the number of fast operations that have been announced in the past. This sequence number is used by processes to determine whether an announced fast operation is pending execution. Initially $fastOp$ is $(\bot, 0)$. The methods $doFast()$ and $doSlow()$ make use of two private methods $helpFast()$ and $f()$ (see Figure 6).

**Description of the $f()$ method.** Method $f()$ is implemented using the specification provided by type $T$. The method takes two arguments $state_1$ and $op$, where $state_1$ is a state of object $O$ and $op$ is the complete description of an operation to be applied on object $O$. The method computes the new state $state_2$ and the result $result$, when operation $op$ is applied on object $O$ with state $state_1$. The method then returns the pair $(state_2, result)$. Since no shared memory operations are executed during the method, the method has 0 step complexity.

**Description of the $doFast()$ method.** Let $p$ be a process that executes $doFast(op)$. In line 1 process $p$ first copies the 4-tuple read from register $mReg$ to its local variables $state, res, fc$ and $sc$. Then $p$ announces the operation $op$ by writing the pair $(op, fc + 1)$ to register $fastOp$ in line 2. After announcing the operation, process $p$ helps perform the announced operation by calling the private method $helpFast()$ in line 3. If the call to $helpFast()$ returns $false$, then $p$ concludes that the announced operation may not have been performed yet. In this case $p$ makes another call to $helpFast()$ in line 3 to be sure that the announced operation is performed (we prove later that at most two calls to $helpFast()$ are required to perform an announced operation). Process $p$ then reads and returns the result of the performed operation stored in $mReg[1]$ in line 4 and 5 respectively. Since method $doFast()$ is not executed concurrently (by assumption), the result of $p$’s operation stored in register $mReg$ is not overwritten before the end of $p$’s $doFast(op)$ call.

**Description of the $helpFast()$ method.** Let $q$ be a process that calls and executes $helpFast()$. In line 6 process $q$ first copies the 4-tuple read from register $mReg$ into its local variables $s_1, r_1, fc$ and $sc$. The value read from $mReg[0]$ constitutes the state of object $O$, to which $q$ will attempt to apply the announced operation if required. The value read from $mReg[1]$ is the result of the last fast operation performed on object $O$. The value read from $mReg[2]$ and $mReg[3]$ is the count of the number of fast and slow operations performed respectively. Process $q$ then reads $fastOp$ in line 10 to find out the announced operation $op$ and the announced sequence number $seq$. Process $q$ then determines whether the announced operation has already been performed, by checking whether $seq$ is less than or equal to $fc$ in line 11. If so, $q$ concludes that operation $op$ has been performed and returns $true$, otherwise it attempts to perform $op$ in lines 12 and 13. In line 12 process $q$ calls the private method $f()$ to compute the new state $s_2$ and the result $r_2$ when operation $op$ is applied to object $O$ with state $s_1$. In line 13 process $p$ attempts to perform $op$ by swapping the 4-tuple $(s_1, r_1, fc, sc)$ with $(s_2, r_2, fc + 1, sc)$ using a $CAS$ operation on $mReg$. If the $CAS$ is unsuccessful then no changes are made to $mReg$. This can happen only if some other process performs an announced fast operation in line 13 or a slow operation in line 19. The result of the $CAS$ operation of line 13 is returned in either case.

**Description of the $doSlow()$ method.** Let $p$ be a process that calls and executes $doSlow(op)$. During the method, $p$ repeats the while-loop of lines 15-19 until $p$ is able to successfully apply its operation $op$. In line 15 process $p$ first copies the 4-tuple read from register $mReg$ to its local variables $s_1, r_1, fc$ and $sc$. In line 16 process $q$ calls the private method $f()$ to compute the new state $s_2$ and the result $r_2$ when operation $op$ is applied to object $O$ with state $s_1$. In the case that operation $op$ does not cause a state change in object $O$, i.e., $s_1 = s_2$, then $p$ returns result $r_2$ in line 17. Otherwise $p$ attempts to apply operation $op$ in line 19 by swapping the 4-tuple
(s1, r1, fc, sc) with (s2, r2, fc, sc + 1) using a CAS operation on register mReg. Before attempting to apply its own operation in line 19, p makes a call to helpFast() in line 18 to help perform an announced fast operation (if any). On completing the while-loop, p would have successfully applied its operation op, and thus p returns the result of the applied operation in line 20.

The following lemma (proven in Section C.2) summarizes the properties of object SFMSUnivConstWeak(T).

**Lemma C.1.** Object SFMSUnivConstWeak(T) is a lock-free universal construction object that implements an object O of type T, for n processes, where n is the maximum number of processes that can access object SFMSUnivConstWeak(T) concurrently and operations on object O are performed using either method doFast() or doSlow(), and no two processes execute method doFast() concurrently. Method doFast() has O(1) step complexity.

### C.1 Operation Combining Technique

In principle the technique works as follows: Processes maintain an N-element array, say announce, where process i “owns” slot i, and processes store in their respective slots the operation that they want to apply. When a process p wants to apply an operation it first “announces” its operation by writing the operation to the p-th element of the array. Then p attempts to help the “next” operation in the announce array by attempting to apply that operation if it has not been applied, yet. An index to the “next” operation to be applied is maintained in the same register that stores the state of the concurrent object. Every time an announced operation is applied, the index is also incremented modulo N in one atomic step. The response of applied operations is stored in another N-element array, say response, which can sometimes be combined with the announce array. Sequence numbers are used to ensure that an announced operation is not applied more than once. Since the index of the “next” operation cycles the announce array, a process needs to help announced operations O(N) times before its own announced operation is applied, at which point it can stop.

Herlihy [18] introduced this technique as a general methodology to transform lock-free universal constructions to wait-free ones. Herlihy presents another example [19] that employs the technique of operation combining to transform a lock-free universal construction to a wait-free one, where the step complexity of the method that performs the operation is bounded to O(N).

On applying the standard technique of operation combining [18] to object SFMSUnivConstWeak(T) we obtain object SFMSUnivConst(T) and Lemma C.2.

### C.2 Analysis and Proofs of Correctness of Object SFMSUnivConstWeak(T)

Let a helpFast() method call that returns true in line 13 (on executing a successful CAS operation) be called a successful helpFast().

**Claim C.2.** (a) The value of fastOp[1] changes only in line 2.

(b) The value of mReg[3] increases by one with every successful CAS operation in line 19 and no other operation changes mReg[3].

(c) The value of mReg[2] increases with every successful CAS operation in line 13 (during a successful helpFast()), and no other operation changes mReg[2].

**Proof.** Part (a) follows immediately from an inspection of the code. Register mReg is changed only when a process executes a successful CAS operation in lines 13 or 19. Furthermore, in line 13 mReg[3] is not changed and in line 19 mReg[2] is not changed. Since, in line 19 mReg[3] is incremented...
Part (b) follows immediately. Now, for a process to execute line $13$, the if-condition of line $11$ must fail, hence $mReg[2]$ is increased from its previous value and Part (c) follows.

Consider an arbitrary history $H$ where processes access an SFMSUnivConstWeak$(T)$ object but no two $\text{doFast}()$ method calls are executed concurrently. Since the fast operations are executed sequentially the happens before order on all $\text{doFast}()$ method calls in $H$ is a total order.

Claim C.3. Let $u_t$ be the $t$-th $\text{doFast}()$ method call in history $H$ being executed by process $p_t$. For $t \geq 1$ let $\alpha_t$ be the point in time when $p_t$ executes line $2$ during $u_t$ and $\gamma_t$ be the point when $p_t$ is poised to execute line $4$. Let $u_t$’s helpers be the processes that call $\text{helpFast}()$ such that the value read by the processes in line $10$ is the value written to register $\text{fastOp}$ at $\alpha_t$. Let $\beta_t$ be the first point in time when a helper’s call to $\text{helpFast}()$ succeeds after $\alpha_t$. Let $\alpha_0, \beta_0, \gamma_0$ be the start of execution $H$. Then the following claims hold for all $t \geq 0$:

$(S_1)$ $\beta_t$ exists and $\beta_t$ is in $(\alpha_t, \gamma_t)$

$(S_2)$ Throughout $(\alpha_t, \beta_t)$: $\text{fastOp}[1] = mReg[2] + 1 = t$

$(S_3)$ Throughout $(\beta_t, \alpha_{t+1})$: $\text{fastOp}[1] = mReg[2] = t$

Proof. We prove claims $(S_1), (S_2)$ and $(S_3)$ by induction over $t$.

Basis: For $t = 0$, $(S_1)$ and $(S_2)$ are trivially true. By assumption the initial value of $\text{fastOp}[1]$ and $mReg[2]$ is $0$. Consider the interval $(\beta_0, \alpha_1)$. From Claim $[C.2]$ it follows that $\text{fastOp}$ is written for the first time at $\alpha_1$. The first point when one of the invariants $(S_3)$ is destroyed is if a process (say $p$) executes a successful $\text{CAS}$ operation in line $13$ during $(\beta_0, \alpha_1)$. Then $p$ reads the value $0$ from register $\text{fastOp}[1]$ in line $10$ since the initial value of $\text{fastOp}[1]$ is $0$ and $\text{fastOp}[1]$ is written to for the first time at $\alpha_1$. Since $mReg[2]$ is never decremented (from Claim $[C.2]$) and $mReg[2]$ initially has value $0$, $p$ satisfies the if-condition of line $11$ and $p$’s $\text{helpFast}()$ call returns $\text{true}$ in line $11$. Therefore, $p$ does not execute line $13$ which is a contradiction.

Induction Step: For $t \geq 1$:

Proof of $(S_1)$: Consider the interval $(\alpha_t, \gamma_t)$. To show that $(S_1)$ holds for $t$, we need to show that $mReg[2]$ is changed during $(\alpha_t, \gamma_t)$. Consider $p_t$’s first call to $\text{helpFast}()$ in line $8$ during $u_t$. From induction hypothesis $(S_3)$ for $t - 1$, it follows that $\text{fastOp}[1] = mReg[2] = t - 1$ during $(\beta_{t-1}, \alpha_t)$. Then $p_t$ reads value $t - 1$ from $mReg[2]$ in line $11$ and writes value $t$ to $\text{fastOp}[1]$ in line $2$. Since $\text{fastOp}[1]$ is changed only at $\alpha_{t+1}$ after $\alpha_t$, it follows that $p_t$ reads $t$ from register $\text{fastOp}[1]$ in line $10$.

Case $a$ - $p_t$ returns from line $11$. Then $p_t$ read a value from $mReg[2]$ in line $9$ that is at least $t$. Since $mReg[2] = t - 1$ holds immediately before $\alpha_t$ some process changed $mReg[2]$ in line $13$ during $(\alpha_t, \gamma_t)$. Hence, $(S_1)$ for $t$ holds.

Case $b$ - $p_t$ returns $\text{true}$ from line $13$. Then $p_t$ has changed $mReg[2]$ and hence $(S_1)$ holds for $t$.

Case $c$ - $p_t$ returns $\text{false}$ from line $13$. Then some process $q$ changed register $mReg$ after $p_t$ read $mReg$ in line $9$. Now, register $mReg$ is written to only in line $13$ or line $19$ (from an inspection of the code).

Subcase $c1$ - $q$ changed $mReg$ by executing line $13$. Then $q$ has changed $mReg[2]$ and hence $(S_1)$ holds for $t$.

Subcase $c2$ - $q$ changed $mReg$ by executing line $19$. Then $p_t$ executes a second call to $\text{helpFast}()$ in line $3$. Let $m$ be the value of $mReg[3]$ read by $p_t$ in line $9$. If $p_t$’s second $\text{helpFast}()$ call satisfies case (a) or (b) then we get that $(S_1)$ holds for $t$.\vfill\eject
If $p_t$’s second `helpFast()` call returns `false` from line 13, then some process changed $mReg$ after $p_t$ read $mReg$ in line 9. If some process changed $mReg$ by executing line 13 then we get that $(S_1)$ holds for $t$. Then some process changed $mReg$ by executing line 19 after $p_t$ read $mReg$ in line 9 and let $r$ be the first process to do so. Therefore, $r$ changes the value of $mReg[3]$ from $m$ to $m + 1$ in line 19. Then $r$ executed line 13 after $q$ executed a successful `CAS` operation in line 19. Then $r$ completed a call to `helpFast()` in line 18 after $\alpha_t$. Since $r$ reads $mReg$ after $\alpha_t$, $r$ satisfied the if-condition of line 11 and executed line 13. If $r$ successfully executes the `CAS` operation in line 13 then we get that $(S_1)$ holds for $t$. Then some process $s$ must have changed $mReg$ after $r$ read $mReg$ in line 9. Since the value of $mReg[3]$ is only incremented (by Claim C.2(b)) and $r$ changes the value of $mReg[3]$ from $m$ to $m + 1$, it follows that $s$ changed $mReg$ in line 13 and hence $(S_1)$ holds for $t$.

**Proof of $(S_2)$ and $(S_3)$:** From $(S_1)$ for $t$ it follows that $\beta_t$ exists and $\alpha_t < \beta_t < \gamma_t < \alpha_{t+1}$. From the induction hypothesis invariants $(S_2)$ and $(S_3)$ are true until $\alpha_t$. Now, one of the invariants $(S_2)$ or $(S_3)$ can be destroyed only if some process executes a successful `CAS` operation in line 13 and changes $mReg[2]$. By definition of $\beta_t$, $mReg[2]$ is unchanged during $(\alpha_t, \beta_t)$. Then invariants $(S_2)$ and $(S_3)$ continue to hold until $\beta_t$. Therefore, claim $(S_2)$ holds for $t$. It still remains to be shown that claim $(S_3)$ holds for $t$.

Let $p$ be the process that executes a successful `CAS` operation in line 13 and changes $mReg[2]$ at $\beta_t$. Since $mReg[2] = t - 1$ immediately before $\beta_t$ and $p$ executes a successful `CAS` operation in line 13 at $\beta_t$, $p.fc = t - 1$. Then $p$ executed lines 9 and 10 during $(\alpha_t, \beta_t)$ and $p.seq = t$. Therefore, invariant $(S_3)$ is true immediately after $\beta_t$.

Now, assume another process (say $q$) destroys one of the invariants $(S_3)$ or $S_4$ by executing a successful `CAS` operation in line 13 during $(\beta_t, \alpha_{t+1})$. Then $q$ must have read register $mReg[2]$ and `fastOp`[1] after $\beta_t$, and therefore $q$ must read the value $t$ from both of them. Then $q$ must have satisfied the if-condition of line 11 and returned `true`. Hence, $q$ does not execute line 13 which is a contradiction. Therefore, invariant $(S_3)$ is true up to $\alpha_{t+1}$, and thus claim $(S_3)$ holds for $t$. \[ \]

Let $H'$ be a history that consists of all completed method calls in $H$ and all pending method calls that executed line 2 (`Write` operation on register `fastOp`), or which executed a successful `CAS` operation in line 13 or line 19. We omit all other pending method calls, since during those method calls no operations are executed that changes the state of any shared object, and hence those pending method calls cannot affect the validity of any other operation. Therefore, to prove that history $H$ is linearizable it suffices to prove that history $H'$ is linearizable.

For each method call $u$ in $H'$, we define a point $pt(u)$ and an interval $I(u)$. Let $I(u)$ denote the interval between $u$’s invocation and response. If $u$ is a `doSlow()` method call that returns from line 17 then $pt(u)$ is the point in time of the `Read` operation in line 15 otherwise, $pt(u)$ is the point in time of the `CAS` operation in line 19. If $u$ is a `doFast()` method call, let $v$ be a successful `helpFast()` method call such that $v$’s line 13 is executed after $u$’s line 2 and before $u$ returns. We define $pt(u)$ to be the point of the successful `CAS` operation in $v$’s line 13.

**Claim C.4.** For every method call $u$ in $H$, $pt(u)$ exists and lies in $I(u)$.

**Proof.** There are two types of method calls in $H$, `doFast()` and `doSlow()`.

**Case a -** $u$ is a `doFast()` method call.

From Claim C.3 it follows that exactly one of $u$’s helpers (see Claim C.3 for definition) succeeds and the helper performs a successful `CAS` operation in line 13 at some point in $I(u)$. Therefore, point $pt(u)$ exists and lies in $I(u)$.

**Case b -** $u$ is a `doSlow()` method call. By definition $pt(u)$ is assigned to a line of $u$’s code, therefore $pt(u)$ exists and lies in $I(u)$. \[ \]
Let \( S \) be the sequential history obtained by ordering all method calls \( u \) in \( H' \) according to the points \( pt(u) \). To show that \( \text{SFMSUnivConstWeak}(T) \) is a linearizable implementation of an object \( O \) of type \( T \), we need to show that the sequential history \( S \) is valid, i.e., \( S \) lies in the specification of type \( T \), and that \( pt(u) \) lies in \( I(u) \) (already shown in Claim C.4). Let \( S_v \) be the sequential history obtained when the operations of \( S \) are executed sequentially on object \( O \), as per their order in \( S \). Clearly, \( S_v \) is a valid sequential history in the specification of type \( T \) by construction. Then to show that \( S \) is valid, we show that \( S = S_v \).

Let \( v_t \) be the \( t \)-th operation in \( S_v \) and let \( u_t \) be the \( t \)-th method call in \( S \). Let \( UC_t^- \) and \( UC_t^+ \) denote the value of \( mReg[0] \) immediately before and after \( pt(u_t) \), respectively. Let \( O_t^- \) and \( O_t^+ \) denote the state of object \( O \) immediately before and after operation \( v_t \), respectively. Let \( \alpha_t \) and \( \beta_t \) denote the value returned by \( u_t \) and \( v_t \), respectively. Define \( UC_0^+ = UC_1^- \) and \( O_0^+ = O_1^- \). Define \( \alpha_0 = \beta_0 = \bot \).

**Claim C.5.** Suppose a process calls method \( f(x_1, \text{op}) \) and the method returns the value pair \( (x_2, y) \). If \( x_1 = O_t^- \) then \( x_2 = O_t^+ \) and \( y = \beta_t \).

**Proof.** By definition, a call to method \( f(x_1, \text{op}) \) returns the value pair \( (x_2, y) \) such that \( x_2 \) is the state of \( O \) when operation \( \text{op} \) is applied to \( O \) while at state \( x_1 \) and \( y \) is the result of the operation. Then if \( x_1 = O_t^- \) then \( x_2 = O_t^+ \) and \( y = \beta_t \). \( \square \)

**Claim C.6.** For all \( t \geq 1 \).

\[
\begin{align*}
(S_1) & \quad O_t^+ = O_{t+1}^- \text{ and } UC_t^+ = UC_{t+1}^- \\
(S_2) & \quad UC_t^- = O_t^- \\
(S_3) & \quad UC_{t+1}^- = O_{t+1}^- \text{ and } \alpha_{t-1} = \beta_{t-1}
\end{align*}
\]

**Proof.** **Proof of (S1):** Since operations in \( S_v \) are executed sequentially, it follows that \( O_t^+ = O_{t+1}^- \). We now show that \( UC_t^+ = UC_{t+1}^- \). Assume \( UC_t^+ \neq UC_{t+1}^- \). Then some process \( p \) changed the value of \( mReg[0] \) by executing a successful \texttt{CAS} operation in line 13 or line 19 at some point during the interval \( (pt(u_t), pt(u_{t+1})) \). By definition, \( p \)'s successful \texttt{CAS} operation in line 13 or line 19 is \( pt(u_t) \) for some method call \( u_t \) where \( u_t \) is the \( \ell \)-th method call in \( H' \). Thus, \( \ell \) is an integer and \( t < \ell < t+1 \) holds, which is a contradiction.

**Proof of (S2) and (S3):** We prove (S2) and (S3) by induction over \( t \).

**Basis** \( (t = 1) \) - By assumption, initially, \( mReg[0] \) is the initial state of \( O \), hence, \( UC_1^- = O_1^- \). Hence, (S2) is true. (S3) is true trivially.

**Induction Step** - We assume (S2) and (S3) for \( t \) are true and prove that (S2) and (S3) for \( t+1 \) are true. From (S1) we have, \( O_t^+ = O_{t+1}^- \) and \( UC_t^+ = UC_{t+1}^- \). From (S2) for \( t \) we have \( UC_t^- = O_t^+ \). Therefore, it follows that \( UC_{t+1}^- = O_{t+1}^+ \) and thus (S2) for \( t+1 \) is true.

To show (S3) for \( t+1 \) is true, we need to show \( UC_t^+ = O_t^- \) and \( \alpha_t = \beta_t \). By Claim (S2) for \( t \), \( UC_t^- = O_t^- \) holds. Let \( p_t \) be the process executing \( u_t \).

**Case a** - \( u_t \) is a \texttt{doSlow(\text{op})} method call: Let \( x_1 \) be the most recent value read by \( p_t \) from \( mReg[0] \) in line 15 and let \( (x_2, y) \) be the value returned when \( p_t \) executes line 16. From the code structure, \( \alpha_t = y \).

**Subcase (a1)** - \( p_t \) returns from line 17 Then \( pt(u_t) \) is the point when \( p_t \) executes a successful \texttt{Read} operation on register \( mReg \) in line 15. Since \( p \) satisfies the if-condition of line 17, \( x_2 = x_1 \). Thus, \( UC_t^- = UC_t^+ = x_1 \).

**Subcase (a2)** - \( p_t \) returns from line 20 Then \( pt(u_t) \) is the point when \( p_t \) executes a successful \texttt{CAS} operation on register \( mReg \) in line 19. From the definition of a \texttt{CAS} operation, it follows that \( UC_t^- = x_1 \) and \( UC_t^+ = x_2 \).

24
For both subcases (a1) and (a2), \( x_1 = UC^- = O^- \) holds. Then from Claim C.5 it follows that \( x_2 = O^+ \) and \( y = \beta_t \). Since \( x_2 = UC^+_t \) and \( y = \alpha_t \), \( O^+_t = UC^+_t \) and \( \alpha_t = \beta_t \).

Case b - \( u_t \) is a doFast(op) method call: Then \( pt(u_t) \) is the point when a successful CAS operation on register \( mReg \) is executed in line 14 of method call \( w \) where \( w \) is the first successful helpFast() method call that begins after \( u_t \)’s line 2 is executed. Let \( q \) be the process executing \( w \). Let \( x_1 \) be the value read by \( q \) from \( mReg[0] \) in line 9 and let \( (x_2, y) \) be the value returned when \( q \) executes line 12. From the definition of a CAS operation, it follows that \( UC^-_t = x_1 \) and \( UC^+_t = x_2 \). Since \( x_1 = UC^-_t = O^-_t \), from Claim C.5 it follows that \( x_2 = O^+_t \) and \( y = \beta_{u_t} \). Since \( x_2 = UC^+_t \), it follows that \( O^+_t = UC^+_t \).

From Claim C.3 if follows that \( mReg[1] \) is changed exactly once during \( u_t \), specifically at \( pt(u_t) \), where \( q \) writes the value \( y \) to it. Thus, \( p \) reads the value \( y \) from \( mReg[1] \) in line 4 since \( p \) executes line 3 after \( pt(u_t) \) (Claim C.3). Therefore, it follows that \( \alpha_{u_t} = y = \beta_{u_t} \).

Lemma C.7. History \( H' \) has a linearization in the specification of \( T \).

Proof. By Claim C.4, for each method call \( u \) in \( H' \), \( pt(u) \) exists and lies in \( I(u) \). Thus, to show that \( H' \) is linearizable we only need to show that \( S \) lies in the specification of type \( T \). Thus, we need to show that for all \( t \geq 1 \), the value returned by \( v_t \) matches that value returned by \( u_t \). From Claim C.6 \((S_3)\) it follows that for all \( t \geq 1 \), \( \alpha_t = \beta_t \).

Lemma C.8. Object SFMSUnivConstWeak\( T \) is lock-free.

Proof. Suppose not. I.e., there exists an infinite history \( H \) during which processes take steps but no method call finishes. It is clear from an inspection of method doFast() and private method helpFast(), that both methods are wait-free. Then if \( H \) contains steps executed by a process that executes a call to doFast() then the doFast() method call finishes since processes continue to take steps in history \( H \) – a contradiction. Now consider the only other case, where history \( H \) contains steps executed by processes only on doFast() method calls. Consider a process \( p \) that takes steps in history \( H \) and fails to complete its doSlow() method call. Then during \( p \)’s execution \( p \) reads register \( mReg \) in line 14 and fails its CAS operation in line 19 during an iteration of the loop of lines 14-19. Now \( p \)’s CAS operation can fail only if some process executes a successful CAS operation in line 13 or line 19 between \( p \)’s Read() and CAS operation.

Case a - Some process \( q \) executes a successful CAS operation in line 19. Then \( q \) breaks out of the loop of lines 14-19. Since processes continue to take steps in our infinite history \( H \), \( q \) eventually returns from its doSlow() method call – a contradiction.

Case b - Some process \( q \) executes a successful CAS operation in line 13. Then \( q \) has performed a successful helpFast() method call and incremented \( mReg[2] \). Let the value of \( mReg[2] \) after the increment be \( z \). Now consider the next iteration of the loop by process \( p \), where \( p \)’s CAS operation in line 19 fails again. Since Case a leads to a contradiction, some process \( r \) executed a successful CAS operation in line 13. Then \( r \) read incremented \( mReg[2] \) to some value greater than \( z \) in line 13. From the code structure of the helpFast() method, \( r \) failed the if-condition of line 11 and therefore \( r \) read \( seq = fastOp[1] > z \) in line 10. Since fastOp[1] is incremented only in line 2 during a doFast() method call, it follows that a doFast() method was called after \( q \) incremented \( mReg[2] \) to \( z \) in line 19. This is a contradiction to the assumption that processes take steps executing only method doSlow() during our history \( H \).

Lemma C.7 follows from Lemma C.7 and C.8.
D The Array Based Randomized Abortable Lock

D.1 Implementation / Low Level Description

We now describe the implementation of our algorithm in detail. (See Figure 1 and 2). We now
describe the method calls in detail and illustrate the use of each of the internal objects as and when
we require them.

The \texttt{lock()} method. Suppose \( p \) executes a call to \texttt{lock()}(). Process \( p \) first receives a sequence
number using a call to \texttt{getSequenceNo()} in line 1 and stores it in its local variable \( s \). Method
\texttt{getSequenceNo()} returns integer \( k \) on being called for the \( k \)-th time from a call to \texttt{lock()}(). Since calls to
\texttt{lock()}() are executed sequentially, a sequential shared counter suffices to implement
method \texttt{getSequenceNo()}(). Method \texttt{getSequenceNo()}() is used to return unique sequence number
which helps solve the classic ABA problem. The ABA problem is as follows: If a process reads an
object twice and reads the value of the object to be 'A' both times, then it is unable to differentiate
this scenario from a scenario where the object was changed to value 'B' in between the two reads
of the object. Process \( p \) then spins on \texttt{apply}[i] in line 2 until \( p \) registers itself by swapping the value
\( ⟨\text{REG}, s⟩ \) into \texttt{apply}[i] using a \texttt{CAS} operation. Processes write the value \texttt{REG} in the \texttt{apply}
array to announce their presence at lock \( L \).

Process \( p \) then executes the role-loop, lines 4 and 12 until \( p \) either increases the value of \texttt{Ctr} to 1 or
2, or until \( p \) is notified of its promotion. Process \( p \) begins an iteration of the role-loop by calling
the \texttt{Ctr.inc()} operation in line 5 and stores the returned value into \texttt{Role}[i]. The returned value
determines \( p \)'s current role at lock \( L \). The shared array \texttt{Role} is used by process \( p \) to store its role in
slot \texttt{Role}[i], which can later be read to determine the actions to perform at lock \( L \). This is important
because we want to allow the behavior of transferring locks. Specifically, to enable a process \( q \) to
call \texttt{release}() on behalf of \( p, q \) needs to determine \( p \)'s role at lock \( L \), which is possible by reading
\texttt{Role}[i].

If the \texttt{Ctr.inc()} operation in line 5 fails, i.e., it returns \( ⊥ \), then \( p \) repeats the role-loop. Such
repeats can happen only a constant number of times in expectation (by Claim A.2). If the value
returned in line 5 is 0 or 1, then \( p \) has incremented the value of \texttt{Ctr} (from the semantics of a
\texttt{RCAScounter} object), and it becomes \texttt{king}_L or \texttt{queen}_L, respectively, and breaks out of the role-loop
in line 12.

If \( p \) becomes \texttt{king}_L in line 5 then \( p \) fails the if-condition of line 13 and proceeds to execute
lines 16 and 17. In line 16 \( p \) changes \texttt{apply}[i] to the value \( ⟨\text{PRO}, s⟩ \), to prevent itself from getting
promoted in future promote actions. In line 17 \( p \) returns from its \texttt{lock()} call by returning the
special value \( ∞ \) (a non-\( ⊥ \) value indicating a successful \texttt{lock()} call), since \( p \) is \texttt{king}_L.

If \( p \) becomes \texttt{queen}_L in line 5 then \( p \) knows that there exists a king process at lock \( L \), and
thus \texttt{queen}_L proceeds to spin on \texttt{Sync1} in line 14 awaiting a notification from \texttt{king}_L. Recall that
\texttt{king}_L notifies \texttt{queen}_L of \texttt{queen}_L’s turn to own lock \( L \) by writing the integer \( j \) into \texttt{Sync1} during a
\texttt{release}(j) call. Once \( p \) receives \texttt{king}_L’s notification (by reading a non-\( ⊥ \) value in \texttt{Sync1} in line 14),
\( p \) breaks out of the spin loop of line 14 and proceeds to execute lines 16 and 17. In line 16 \( p \) changes
\texttt{apply}[i] to the value \( ⟨\text{PRO}, s⟩ \), to prevent itself from getting promoted in future promote actions.
In line 17 \( p \) returns from its \texttt{lock()} call by returning the integer value stored in \texttt{Sync1} (a non-\( ⊥ \)
value indicating a successful \texttt{lock()} call).

If the value returned in line 5 is 2, then \( p \) does not become \texttt{king}_L or \texttt{queen}_L, and thus \( p \)
assumes the role of a pawn. Process \( p \) then waits for a notification of its own promotion, or, for the \texttt{Ctr}
value to decrease from 2, by spinning on \texttt{apply}[i] and \texttt{Ctr} in line 7. When \( p \) breaks out of this spin
lock, it determines in line 8 whether it was promoted by checking whether the value of \texttt{apply}[i]
was changed to \( ⟨\text{PRO}, s⟩ \). A process is promoted only by a \texttt{king}_L, \texttt{queen}_L or a \texttt{ppawn}_L during their
release() call. If p finds that it was not promoted, then p is said to have been missed during a Ctr-cycle, and thus p repeats the role-loop. We later show that a process gets missed during at most one Ctr-cycle.

If p was promoted, then it writes a constant value PAWN_P = 3 into Role[i] in line 9 and becomes ppawnᵢL. Since p has been promoted, p knows that both kingᵢL and queenᵢL are no longer executing their entry or Critical Section, and thus p owns lock L now. Then p goes on to break out of the role-loop in line 12 and proceeds to return from its lock() call by returning the special value ∞ (a non-⊥ value indicating a successful lock() call), since p is ppawnᵢL.

The release() method. Suppose p executes a call to releaseᵢ(j) with an integer argument j. We restrict the execution such that a process calls a releaseᵢ(j) method only after a call to a successful lock() has been completed.

In line 34, p initializes the local variable r to the boolean value false. Local variable r is returned later in line 50 to indicate whether the integer j was successfully written to Sync1 during the release method call. In lines 35, 42, and 45, process p determines its role at the node and the action to perform. In line 49, process p deregisters itself from lock L by swapping ⟨⊥, ⊥⟩ into apply[i]. At the end of the method call a boolean is returned in line 50 indicating whether the integer j was written to Sync1.

If p determines that it is kingᵢL, then it attempts to decrease Ctr from 1 to 0 in line 36. This decrement operation will only fail if there exists a queen process at lock L which increased the Ctr to 2 during its lock() call. If the decrement operation fails then p has determined that there exists a queen process at lock L and it now synchronizes with queenᵢL to perform the collect action. Recall that CAS object Sync1 is used by kingᵢL and queenᵢL to determine which process performs a collect. In line 37, p attempts to swap integer j into Sync1 by executing a Sync1.CAS(⊥, j) operation and stores the result of the operation in local variable r. If p is successful then it performs the collect action by executing a call to doCollectᵢ() in line 38. If p is unsuccessful then it knows that queenᵢL will perform a collect. In line 39, p calls the helpReleaseᵢ() method to synchronize the release of lock L with queenᵢL. We describe the method helpRelease() shortly.

If p determines that it is queenᵢL, then it calls the helpReleaseᵢ() method call in line 43 to synchronize the release of lock L with kingᵢL.

If p determines that it is a promoted pawn, then it attempts to promote a waiting pawn by making a call to doPromote() in line 46.

The doCollect() method. Suppose a process p executing a doCollectᵢ() method call. The collect action consists of reading the array (left to right), and creating a vector A of n values, where the k-th element is either ⊥ (to indicate that the process with pseudo-ID k is not a candidate for promotion) or an integer sequence number (to indicate that the process with pseudo-ID k is a candidate for promotion). The vector A is stored in the PawnSet in line 53 using a PawnSet.collect(A) operation. The PawnSet.collect(A) operation ensures that if the k-th element of PawnSet has value 3 = ABORT (written during a PawnSet.abort(k, ·) operation), then the k-th element is not overwritten during the PawnSet.collect(A) operation. This is required to ensure that processes that have expressed a desire to abort are not collected and subsequently promoted.

The helpRelease() method. Suppose kingᵢL calls helpReleaseᵢ() and queenᵢL calls helpReleaseᵢ(). During the course of these method calls, kingᵢL and queenᵢL synchronize with each other in order to reset CAS objects Sync1 and Sync2, remove themselves from PawnSet, promote a collected process and notify the promoted process. If no process is found in PawnSet that can be promoted, then the PawnSet object is reset to its initial state and Ctr reset to 0. Recall that CAS object Sync2 is used as a synchronization primitive by kingᵢL and queenᵢL to determine which process exits last among them, and thus performs all pending release work. In line 56, the process
which swaps value $i$ or $k$ into Sync2 by executing a successful CAS operation, exits, and the other process performs the pending release work in lines 57-63. Let us now refer to this other process as the releasing process. In lines 57-58, the releasing process resets Sync1 to its initial value $\bot$. In line 59, the releasing process reads the pseudo-ID written to Sync2 by the exited process (process that executed a successful CAS operation on Sync1). The pseudo-ID written to Sync2 is required to remove the exited process from getting promoted in a future promote in case it was collected in PawnSet. In line 61, the releasing process removes the exited process from PawnSet. CAS object Sync2 is reset to its initial value $\bot$ in line 60. In line 62, the releasing process calls doPromote() to promote a collected process.

**The doPromote() method.** Suppose $p$ executes a call to doPromote$_i()$. In line 64, $p$ removes itself from PawnSet by executing a PawnSet.remove($i$) operation. It does so to prevent itself from getting promoted in case it was collected earlier. In line 65, $p$ performs a promote action by executing a PawnSet.promote() operation. If a process was collected and the process has not aborted then its corresponding element ($k$-th element for a process with pseudo-ID $k$) in PawnSet will have the value $\langle \text{REG}, \cdot \rangle$. If a process has aborted then its corresponding element in PawnSet will have the value $\langle \text{PRO}, \cdot \rangle$.

If a successful promote() operation is executed then an element in PawnSet is changed from $\langle \text{REG}, s \rangle$ to $\langle \text{PRO}, s \rangle$, where $s \in \mathbb{N}$, and the pair $\langle k, s \rangle$ is returned, where $k$ is the index of that element in PawnSet. In this case we say that process with pseudo-ID $k$ was *promoted*. If an unsuccessful promote() operation is executed, then no element in PawnSet has the value $\langle \text{REG}, s \rangle$, where $s \in \mathbb{N}$, and thus the special value $\langle \bot, \bot \rangle$ is returned. We then say that no process was promoted. The returned pair is stored in local variables $\langle j, \text{seq} \rangle$ in line 65.

If no process was promoted, then $p$ resets PawnSet to its initial value in line 67 using the reset() operation, and decreases Ctr from 2 to 0 in line 68. If a process was found and promoted in PawnSet, then that process is notified of its promotion, by swapping its corresponding apply array element’s value from REG to PRO using a CAS operation in line 70.

Recall that, while executing a lock() method call a process may receive a signal to abort. Suppose a process $p$ receives a signal to abort while executing a lock$_i()$ method call. If process $p$ is busy-waiting in lines 2-7 or 14 then $p$ stops executing lock$_i()$, and instead executes a call to abort$_i()$. If $p$ is poised to execute any line 16 or 17 then it completes its call to lock$_i()$. If $p$ is poised to execute any other line then it continues executing lock$_i()$ until it begins to busy-wait in lines 2-7 or 14 at which point it stops and calls abort$_i()$. If $p$ does not begin to busy-wait in lines 2-7 or 14 then it completes its lock$_i()$ call.

**The abort() method.** Suppose $p$ executes a call to abort$_i()$. Process $p$ first determines whether it quit lock$_i()$ while busy-waiting on apply[i] in line 2 and if so, $p$ returns $\bot$ in line 18. If not, then $p$ changes apply[i] to the value PRO in line 19 to prevent itself from getting collected in future collect actions. In line 20, process $p$ determines whether it quit lock$_i()$ while busy-waiting on apply[i] in line 7 or 14 or while busy-waiting on Sync1 in line 14. If $p$ quit while busy-waiting on apply[i] then clearly it is a pawn process, and if it quit while busy-waiting on Sync1 then it is a queen process.

If process $p$ determines that it is a pawn then it attempts to remove itself from PawnSet by executing a PawnSet.abort($i, s$) operation in line 21, where $s$ was the sequence number returned in line 11. If $p$ has not been promoted yet, then the operation succeeds and $p$’s corresponding element in PawnSet is changed to a value $\langle \text{ABORT}, s \rangle$, thus making sure that $p$ can not be collected or promoted anymore. If $p$ has already been promoted then the operation fails and $p$ now knows that it is has been promoted, and assumes the role of a promoted pawn, and in line 22, $p$ writes PAWN$_P$ into Role[i] and returns the special value $\infty$ in line 23.

If process $p$ determines that it is queen$_L$ then it first attempts to swap a special value $\infty$ into
Sync1 in line 26 by executing a `Sync1.CAS(⊥, ∞)` operation to indicate its desire to abort. If p is successful then p has determined that it is the first (among kingL and itself) to exit, and therefore p performs the collect action by calling `doCollect()` in line 29. Process p then makes a call to `helpRelease()` in line 30 to help release lock L by synchronizing with kingL.

If p was unsuccessful at swapping value ∞ into Sync1 then it knows the kingL is executing `release()`, and kingL will eventually perform the collect action. Then p has determined that it is the current owner of lock L, and returns the integer value stored in Sync1 in line 27.

Process p executes line 32 only if p successfully aborted earlier in its `abort()` call, and thus it deregisters itself from lock L by swapping ⟨⊥, ⊥⟩ into apply[i]. Finally, in line 33 p returns ⊥ to indicate a successful abort (i.e., a failed `lock()` call).

### D.2 Analysis and Proofs of Correctness

Let H be an arbitrary history of an algorithm that accesses an instance, L, of object `ALockArray_n`, where the following safety conditions hold.

**Condition D.1.** (a) No two `lock_i()` calls are executed concurrently for the same i, where i ∈ {0, . . . , n − 1}.

(b) If a process p between t[release] and t[release] step of the Condition D.1.

where the following safety conditions hold. Let

D.2 Analysis and Proofs of Correctness

Methods `release_i(j)`, `abort_i()`, `helpRelease_i()`, `doCollect_i()`, `doPromote()` are wait-free.

**Proof.** Follows from an inspection of these methods. □

**Claim D.3.** No two `release_i()` calls where a shared memory step is pending, are executed concurrently for the same i, where i ∈ {0, . . . , n − 1}.

**Proof.** Assume for the purpose of a contradiction that two processes are executing a call to `release_i()` concurrently for the first time at time t. Then from Condition D.1(b)-(c), it follows that two successful calls to `lock_i()` were executed before t. From condition D.1(a) it follows that the two successful `lock_i()` calls did not overlap. Consider the first successful `lock_i()` call executed by some process p. Since the `lock_i()` call returned a non-⊥ value, the method did not return from line 18. Then p did not abort while busy-waiting in line 2 and thus `apply[i]` was set to a non-⟨⊥, ⊥⟩ value in line 2 after the first `lock_i()` call. Let t be the point in time when `apply[i]` was set to a non-⟨⊥, ⊥⟩ value in line 2. We now show that the `apply[i] ≠ ⟨⊥, ⊥⟩` in the duration between [t', t]. Suppose not, i.e., some process resets `apply[i]` to ⟨⊥, ⊥⟩ during [t', t]. Now, `apply[i]` is reset to a ⟨⊥, ⊥⟩ value only in line 32 during `abort_i()` or in line 49 during `release_i()`.

**Case a -** `apply[i]` reset to ⟨⊥, ⊥⟩ in line 49 during `release_i()`. Then the last shared memory step of the `release_i()` has been executed, and the call has ended for the purposes of the claim. Then the two `release_i()` calls are not concurrent at t, a contradiction.

29
**Case b** - apply\[i\] reset to \(\perp, \perp\) in line 32 during abort\(_i\). Since the two lock\(_i\) calls are not concurrent it follows that apply\[i\] \(\neq \perp, \perp\) at the end of the first lock\(_i\) call, and thus apply\[i\] is reset to \(\perp, \perp\) in line 32 during the second successful lock\(_i\) call. Now consider the second successful lock\(_i\) call executed by some process \(q\). Then \(q\) would repeatedly fail the apply\[i\].CAS(\(\perp, \perp\), ) operation of line 2 and the only way \(q\)'s lock\(_i\) call could finish, is if \(q\) aborts the busy-wait loop of line 2. In which case \(q\) executes abort\(_i\), and satisfies the if-condition of line 18 and return \(\perp\) in line 18. Then the second lock\(_i\) does not reset apply\[i\] in line 32 during abort\(_i\) – a contradiction.

Since apply\[i\] \(\neq \perp, \perp\) throughout \([t', t]\], it then follows from the same argument of **Case b**, that the second lock\(_i\) call is unsuccessful, and thus a contradiction.

From Claim D.3 and Condition D.1(a) it follows that no two calls to lock\(_p\) or release\(_p\) are executed concurrently for the same \(p\), where \(p \in \{0, \ldots, n - 1\}\). Then we can label the process executing a lock\(_p\) or release\(_p\) call, simply \(p\), without loss of generality. We do so to make the rest of the proofs easier to follow.

**Helpful claims based on variable usage.**

**Claim D.4.** (a) Role\[p\] is changed by process \(q\), only if \(q = p\).

(b) Role\[p\] is unchanged during release\(_p\).

(c) Role\[p\] can be set to value KING, QUEEN or PAWN only when \(p\) executes line 5 during lock\(_p\).

(d) Role\[p\] is set to value PAWN\(_P\) only when \(p\) executes line 5 during lock\(_p\) or when \(p\) executes line 22 during abort\(_p\).

**Proof.** All claims follow from an inspection of the code.

**Claim D.5.** (a) The only operations on PawnSet are collect\(_A\), promote\(_\), remove\(_i\), remove\(_j\), abort\(_k, s\) and reset\(_\) (in lines 53, 62, 64, 67, 27 and 77, respectively) where \(A\) is a vector with values in \(\{\perp\} \cup \mathbb{N}\), and \(i, j, k \in \{0, 1, \ldots, n - 1\}\), and \(s \in \mathbb{N}\).

(b) The \(i\)-th entry of PawnSet can be changed to \(\langle\text{REG}, s\rangle\), where \(s \in \mathbb{N}\), only when a process executes a PawnSet.collect\(_A\) operation in line 55 where \(A[i] = s\).

(c) The \(i\)-th entry of PawnSet can be changed to \(\langle\text{PRO}, s\rangle\) = \(\langle2, s\rangle\), where \(s \in \mathbb{N}\), only when a process executes a PawnSet.promote\(_\) operation in line 63.

(d) The \(i\)-th entry of PawnSet can be changed to \(\langle\text{ABORT}, s\rangle\) = \(\langle3, s\rangle\), where \(s \in \mathbb{N}\), only when a process executes a PawnSet.remove\(_i\), PawnSet.remove\(_j\) or PawnSet.abort\(_k s\) operation in lines 64, 61 or 27, respectively.

**Proof.** Part \(\text{[a]}\) follows from an inspection of the code. Parts \(\text{[b]}, \text{[c]}\) and \(\text{[d]}\) follow from Part \(\text{[a]}\) and the semantics of type AbortableProArray\(_n\).

**Claim D.6.** Let \(s \in \mathbb{N}\).

(a) apply\[p\] is changed from \(\perp, \perp\) to a non-\(\perp, s\) value only when process \(p\) executes a successful apply\[p\].CAS(\(\perp, \perp\), \(\langle\text{REG}, s\rangle\)) operation in line 2

(b) apply\[p\] is changed to value \(\langle\text{REG}, s\rangle\) only when process \(p\) executes a successful apply\[p\].CAS(\(\perp, \perp\), \(\langle\text{REG}, s\rangle\)) operation in line 2
(c) \( \text{apply}[p] \) is changed to a \( \langle \bot, \bot \rangle \) value only when \( p \) executes a successful \( \text{apply}[p].\text{CAS(}(\langle \text{PRO}, s \rangle, \langle \bot, \bot \rangle)) \) operation either in line \( 32 \) or line \( 49 \).

Proof. Parts (a), (b) and (c) follow from an inspection of the code. \( \square \)

Helpful Notations and Definitions. We now establish a notion of time for our history \( H \). Let the \( i \)-th step in \( H \) occur at time \( i \). Then every point in time during \( H \) is in \( \mathbb{N} \).

Let \( t^i_p \) denote the point in time immediately after process \( p \) has finished executing line \( i \), and no process has taken a step since \( p \) has executed the last operation of line \( i \) (This operation can be the response of a method call made in line \( i \)). Since some private methods are invoked from more than one place in the code, the point in time \( t^i_p \), where \( i \) is a line in the method, does not refer to a unique point in time in history \( H \). In those cases we make sure that it is clear from the context of the discussion, which point \( t^i_p \) refers to. Let \( t^{i-}_p \) denote the point in time when \( p \) is poised to execute line \( i \), and no other process takes steps before \( p \) executes line \( i \).

Let \( p \) be an arbitrary process and \( s \) be an arbitrary integer. We say process \( p \) registers, when it executes a successful \( \text{apply}[p].\text{CAS(}(\langle \bot, \bot \rangle, \langle \text{REG}, s \rangle)) \) operation in line \( 16 \). Process \( p \) captures and wins lock \( L \) when it returns from \( \text{lock}_p() \) with a non-\( \bot \) value. Process \( p \) is said to promote another process \( q \) if \( p \) executes a \( \text{PawnSet.promote()} \) operation in line \( 65 \) that returns a value \( \langle q, s \rangle \), where \( s \in \mathbb{N} \). A process \( p \) is said to be promoted at lock \( L \), if some process \( q \) executes a \( \text{PawnSet.promote()} \) operation that returns value \( \langle p, s \rangle \), where \( s \in \mathbb{N} \).

Process \( p \) is said to hand over lock \( L \) to process \( q \) if it executes a successful \( \text{CAS} \) operation \( L.\text{Sync1.CAS(}(\langle \bot, s \rangle, j) \) in line \( 67 \) where \( q \) is the process that last increased \( Ctr \) from 1 to 2. Process \( p \) is said to have released lock \( L \) by executing a successful \( \text{Ctr.CAS(}(1, 0) \) operation in line \( 36 \) or by executing a successful \( \text{Ctr.CAS(}(2, 0) \) operation in line \( 68 \). Process \( p \) either hands over, promotes a process, or releases lock \( L \) during a call to \( \text{L.release}_p(j) \) where \( j \) is an arbitrary integer. A process ceases to own a lock either by releasing lock \( L \) or by promoting another process, or by handing over lock \( L \) to some other process. Process \( p \) is deregistered when \( p \) executes a successful \( \text{apply}[p].\text{CAS(}(\langle \text{PRO}, s \rangle, \langle \bot, \bot \rangle)) \) operation in line \( 42 \) or \( 49 \). A process \( p \) is said to be not registered in PawnSet if the \( p \)-th entry of PawnSet is not value \( \langle \text{REG}, s \rangle \), where \( s \in \mathbb{N} \). The repeat-until loop starting at line \( 4 \) and ending at line \( 12 \) is called role-loop.

In some of the proofs we use represent an execution using diagrams, and the legend for the symbols used in the diagrams is given in Figure \( 7 \).

Releasers of lock and Cease-release events.

A process \( p \) becomes a releaser of lock \( L \) at time \( t \) when

(R1) \( p \) increases \( Ctr \) to 1 (i.e., \( \text{Ctr.inc()} \) returns \( 0 = \text{KING} \)) or 2 (i.e., \( \text{Ctr.inc()} \) returns \( 1 = \text{QUEEN} \)), or when

(R2) \( p \) is promoted at lock \( L \) by some process \( q \).

Claim D.7. (a) \( p \) executes a \( \text{Ctr.CAS(}(1, 0) \) operation only in line \( 76 \) during \( \text{release}_p(j) \).

(b) \( p \) executes a \( \text{Sync2.CAS(}(\bot, p) \) operation only in line \( 56 \) during \( p \)’s call to \( \text{helpRelease}_p() \).

(c) \( p \) executes a \( \text{PawnSet.promote()} \) operation only in line \( 65 \) during \( p \)’s call to \( \text{doPromote}_p() \).

(d) \( p \) executes a \( \text{Ctr.CAS(}(2, 0) \) operation only in line \( 68 \) during \( p \)’s call to \( \text{doPromote}_p() \).

Proof. All claims follows from an inspection of the code. \( \square \)

We now define the following cease-release events with respect to \( p \) :
Figure 7: Legend for Figures 8 to 16

- $\ell$: Atomic shared memory operation executed in line $\ell$.
- $\ell$: Method call $m$ executed in line $\ell$.
- $\ell_1 \rightarrow \ell_2$: Operation in line $\ell_2$ is executed only after the operation in line $\ell_1$.
- $\mathcal{P}$: Predicate $\mathcal{P}$ is evaluated in line $\ell$.
  - $\ell$: The next line executed is $\ell_1$ if and only if $\mathcal{P}$ is true.
  - true $\rightarrow \ell_2$: The next line executed is $\ell_2$ if and only if $\mathcal{P}$ is false.
  - false $\rightarrow \ell_1$:
- $\mathcal{P}$: Predicate $\mathcal{P}$ is evaluated in line $\ell$.
  - $\ell$: The next line executed is $\ell_1$ if and only if $\mathcal{P}$ is true.
  - true $\rightarrow \ell_2$: The next line executed is $\ell_2$ if and only if $\mathcal{P}$ is false and condition $C$ is false.
  - false $\rightarrow \ell_1$:
  - $\ell$: The next line executed is $\ell_3$ if and only if $\mathcal{P}$ is false and condition $C$ is true.
- $\ell_1 \rightarrow \ell_2$: Statement $S$ holds after line $\ell_1$ is executed and before line $\ell_2$ is executed.
- $S \rightarrow$: Helpful statement $S$ to improve the readability of the figure.
- $\text{op} \rightarrow \ell$: Operation $\text{op}$ executed in line $\ell$.
\(\phi_p\): \(p\) executes a successful \(\text{Ctr.CAS}(1, 0)\) (at \(p_{36}\) during \(\text{release}_p(j)\)).

\(\tau_p\): \(p\) executes a successful \(\text{Sync2.CAS}(\bot, p)\) (at \(p_{36}\) during \(\text{helpRelease}_p()\)).

\(\pi_p\): \(p\) promotes some process \(q\) (at \(p_{65}\) during \(\text{doPromote}_p()\)).

\(\theta_p\): \(p\) executes an operation \(\text{Crt.CAS}(2, 0)\) (at \(p_{68}\) during \(\text{doPromote}_p()\)).

Process \(p\) ceases to be a releaser of lock \(L\) when one of \(p\)'s cease-release events occurs. We say process \(p\) is a releaser of lock \(L\) at any point after it becomes a releaser and before it ceases to be a releaser.

**Claim D.8.** (a) Method \(\text{doCollect}_p()\) is called only by process \(p\) in lines 29 and 38

(b) Method \(\text{helpRelease}_p()\) is called only by process \(p\) in lines 32 and 30

(c) Method \(\text{doPromote}_p()\) is called only by process \(p\) in line 66 and in line 62 (during \(\text{helpRelease}_p()\)).

(d) If cease-release event \(\phi_p\) occurs then \(p\) is executing \(\text{release}_p(j)\).

(e) If cease-release event \(\tau_p\) occurs then \(p\) is executing \(\text{helpRelease}_p()\).

(f) If cease-release event \(\pi_p\) or \(\theta_p\) occurs then \(p\) is executing \(\text{helpRelease}_p()\) or \(\text{doPromote}_p()\).

**Proof.** Parts (a), (b) and (c) follow from an inspection of the code. By definition, cease-release event \(\phi_p\) occurs when \(p\) executes a successful \(\text{Crt.CAS}(1, 0)\) operation in line \(36\) during \(\text{release}_p(j)\), and thus (a) follows immediately. By definition, cease-release event \(\tau_p\) occurs when \(p\) executes a successful \(\text{Sync2.CAS}(\bot, p)\) in line \(56\) during \(\text{helpRelease}_p()\), and thus (b) follows immediately. By definition, cease-release event \(\pi_p\) occurs only when \(p\) executes a \(\text{PawnSet.promote}(\theta)\) operation that returns a non-near \(-\langle \bot, \bot \rangle\) value in line \(65\) and cease-release event \(\theta_p\) occurs only when \(p\) executes a \(\text{Crt.CAS}(2, 0)\) operation in line \(68\). Then if cease-release event \(\pi_p\) or \(\theta_p\) occurs then \(p\) is executing \(\text{doPromote}_p()\). From (d), \(p\) could also call \(\text{doPromote}_p()\) from line \(62\) during \(\text{helpRelease}_p()\). Then if cease-release event \(\pi_p\) or \(\theta_p\) occurs then \(p\) is executing \(\text{doPromote}_p()\) or \(\text{helpRelease}_p()\). Thus, (f) holds.

**Claim D.9.** Consider \(p\)'s \(k\)-th passage, where \(k \in \mathbb{N}\). Note that \(s = k\). If \(\text{Role}[p] = \text{PAWN}_P\) at some point in time \(t\) during \(p\)'s call to \(\text{lock}_p()\), then some process \(q\) promoted \(p\) at \(t_{q_{60}}\) and \(p\) became releaser of \(L\) by condition (R2) at \(t_{q_{65}} < t\).

**Proof.** From Claim D.4(d), \(p\) changes \(\text{Role}[p]\) to \(\text{PAWN}_P\) only in line 9 or line 22.

**Case a** - \(p\) changed \(\text{Role}[p]\) to \(\text{PAWN}_P\) in line 22 Then \(p\)'s call to \(\text{PawnSet.abort}(p, s)\) returned \text{false} in line 21. From the semantics of the \(\text{AbortableProArray}_p\) object, it follows that the \(p\)-th entry of \(\text{PawnSet}\) was set to value \(\langle \text{PRO}, s \rangle = \langle 2, s \rangle\). From Claim D.5(c), the \(p\)-th entry of \(\text{PawnSet}\) is set to value \(\langle \text{PRO}, s \rangle\) only when a \(\text{PawnSet.promote}(\theta)\) operation returns \(\langle p, s \rangle\) in line 65. Then some process \(q\) promoted \(p\) at \(t_{q_{65}}\) and \(p\) became a releaser of \(L\) by condition (R2) at \(t_{q_{65}} < t\).

**Case b** - \(p\) changed \(\text{Role}[p]\) to \(\text{PAWN}_P\) in line 9 Then \(p\) broke out of the spin loop of line 22 and thus \(\text{apply}[p] = \langle \text{REG}, s \rangle \neq \langle \text{PRO}, s \rangle\) at \(t_{p_{38}}\). Since \(p\) satisfied the if-condition of line 8, it follows that \(\text{apply}[p] = \langle \text{PRO}, s \rangle\) at \(t_{p_{38}}\). Thus, from the code structure, \(p\) also executed a \(\text{PawnSet.promote}(\theta)\) operation that returned \(\langle p, s \rangle\) in line 65. Then \(q\) promoted \(p\) at \(t_{q_{65}}\) and \(p\) became a releaser of \(L\) by condition (R2) at \(t_{q_{65}} < t\).
Claim D.10. Consider p’s k-th passage, where k ∈ N. If t ∈ \{ 18_p, 33_p, 37_p, 39_p, 43_p, 46_p \}, then cease-release event \( \phi_p \) does not occur before time t.

**Proof.** By definition, cease-release event \( \phi_p \) occurs when p executes a successful Ctr.CAS(1,0) operation in line 36. From Claim D.8(d) cease-release event \( \phi_p \) occurs only during release_p(j).

**Case a -** \( t \in 18_p, 33_p \). Then p is executing abort_p() and has not yet executed a call to release_p(). Since cease-release event \( \phi_p \) can occur only during release_p(), cease-release event \( \phi_p \) did not occur before time t.

**Case b -** \( t \in 37_p, 39_p \). Then p executed an unsuccessful Ctr.CAS(1,0) operation in line 36 and cease-release event \( \phi_p \) did not occur before time t.

**Case c -** \( t \in 43_p, 46_p \). From Claim D.11 Role[p] ∈ \{ QUEEN, PAWN_P \} at t. Since Role[p] is unchanged during release_p() (Claim D.4(b)), it follows that Role[p] ≠ KING at \( t \). Then p fails the if-condition of line 35 and does not execute line 36 and thus cease-release event \( \phi_p \) did not occur before time t.

The proof of the following claim has been moved to Appendix F since the proof is long and straightforward.

Claim D.11. The value of Role[p] at various points in time during p’s k-th passage, where k ∈ N, is as follows.

<table>
<thead>
<tr>
<th>Time</th>
<th>Value of Role[p]</th>
<th>Time</th>
<th>Value of Role[p]</th>
</tr>
</thead>
<tbody>
<tr>
<td>20_p</td>
<td>{⊥, KING, QUEEN, PAWN}</td>
<td>23</td>
<td>KING</td>
</tr>
<tr>
<td>43_p</td>
<td>PAWN</td>
<td>21_p</td>
<td>PAWN_P</td>
</tr>
<tr>
<td>13_p</td>
<td>{KING, QUEEN, PAWN_P}</td>
<td>22_p</td>
<td>PAWN</td>
</tr>
<tr>
<td>11_p</td>
<td>QUEEN</td>
<td>21</td>
<td>PAWN_P</td>
</tr>
<tr>
<td>10_p</td>
<td>{KING, QUEEN, PAWN_P}</td>
<td>21</td>
<td>PAWN</td>
</tr>
<tr>
<td>19_p</td>
<td>{QUEEN, PAWN}</td>
<td>19_p</td>
<td>PAWN_P</td>
</tr>
<tr>
<td>17_p</td>
<td>14_p</td>
<td>16_p</td>
<td>QUEEN</td>
</tr>
</tbody>
</table>

Claim D.12. Consider p’s k-th passage, where k ∈ N.

(a) If process p calls helpRelease_p() or doPromote_p() during abort_p() then it does not call release_p(j).

(b) Process p calls helpRelease_p() at most once.

(c) Process p calls doPromote_p() at most once.

**Proof.** Proof of (a): The following observations follow from an inspection of the code. If \( p \) executes doPromote_p() during abort_p(), then it does so during a call to helpRelease_p(.) in line 62. If \( p \) executes helpRelease_p() during abort_p(), then it does so by executing line 30. Then \( p \) calls helpRelease_p(.) or doPromote_p() during abort_p(.) in line 30 and goes on to return value ⊥ in line 33. Then \( p \)'s call to lock_p(.) returns value ⊥ and \( p \) does not call release_p(.) (follows from conditions 8 and 10).
Proof of (b): From Part (a), if \( \text{helpRelease}_p() \) is executed during \( \text{abort}_p() \) then \( \text{release}_p(j) \) is not executed. Then to prove our claim we need to show that \( \text{helpRelease}_p() \) is called at most once during \( \text{abort}_p() \) and \( \text{release}_p(j) \), respectively. From Claim D.8(b), method \( \text{helpRelease}_p() \) is called by \( p \) only in lines 39, 43 and 30. Since \( \text{helpRelease}_p() \) is called only once during \( \text{abort}_p() \) (specifically in line 30), it follows immediately that \( p \) executes \( \text{helpRelease}_p() \) at most once during \( \text{abort}_p() \). From Claim D.11, \( \text{Role}[p] \in \{ \text{KING}, \text{QUEEN}, \text{PAWN}_p \} \) at \( \not\in \). Since \( \text{Role}[p] \) is unchanged during \( \text{release}_p() \) (Claim D.3(b)), it follows that \( p \) satisfies exactly one of the if-conditions of lines 35, 42 and 43 and thus \( p \) does not execute both lines 39 and 43. Then \( p \) executes \( \text{helpRelease}_p() \) at most once during \( \text{release}_p(j) \).

Proof of (c): From Part (a), if \( \text{doPromote}_p() \) is executed during \( \text{abort}_p() \) then \( \text{release}_p(j) \) is not executed. Then to prove our claim we need to show that \( \text{doPromote}_p() \) is called at most once during \( \text{abort}_p() \) and \( \text{release}_p(j) \), respectively. From Claim D.8(a), method \( \text{doPromote}_p() \) is called by \( p \) only in lines 38 and 30. Then \( p \) called \( \text{helpRelease}_p() \) either in line 39, 43 or 30.

Case a - \( p \) called \( \text{doPromote}_p() \) in line 39 (during \( \text{helpRelease}_p() \)). Then \( p \) is executing \( \text{helpRelease}_p() \). From Claim D.8(b), method \( \text{helpRelease}_p() \) is called by \( p \) only in lines 39, 43 and 30. Then \( p \) called \( \text{helpRelease}_p() \) either in line 39, 43 or 30.

Case a(i) - \( p \) called \( \text{helpRelease}_p() \) in line 39 or 43 during \( \text{release}_p(j) \). Then \( p \) is executing \( \text{helpRelease}_p() \), and since \( p \) called \( \text{helpRelease}_p() \) in lines 39 or 43 \( p \) satisfied the if-conditions of lines 35 or 42 and thus \( \text{Role}[p] = \text{KING} \) at \( \not\in \) or \( \text{Role}[p] = \text{QUEEN} \) at \( \not\in \), respectively. Since \( \text{Role}[p] \) is unchanged during \( \text{release}_p() \) (Claim D.3(b)), it follows that \( \text{Role}[p] \in \{ \text{KING}, \text{QUEEN} \} \) during \( \text{release}_p() \). Then \( p \) fails the if-condition of line 43 and does not execute \( \text{doPromote}_p() \) in line 46. Hence, \( p \) executes \( \text{doPromote}_p() \) at most once during \( \text{release}_p() \).

Case a(ii) - \( p \) called \( \text{helpRelease}_p() \) in line 30. Then \( p \) is executing \( \text{abort}_p() \) and it goes on to return value \( \bot \) in line 33. Then \( p \)'s call to \( \text{lock}_p() \) returns value \( \bot \) and \( p \) does not call \( \text{release}_p(j) \) (follows from conditions 13 and 14). Hence, \( p \) executes \( \text{doPromote}_p() \) at most once during \( \text{abort}_p() \).

Case b - \( p \) called \( \text{doPromote}_p() \) in line 36. Then \( p \) is executing \( \text{helpRelease}_p() \) and \( p \) satisfied the if-condition of lines 35 and 43 and thus \( \text{Role}[p] = \text{PAWN}_p \) at \( \not\in \). Since \( \text{Role}[p] \) is unchanged during \( \text{release}_p() \) (Claim D.4(b)), it follows that \( \text{Role}[p] = \text{PAWN}_p \) during \( \text{release}_p() \). Then \( p \) failed the if-condition of lines 35 and 42 and \( p \) did not execute \( \text{helpRelease}_p() \) in lines 39 and 43. Hence, \( p \) executes \( \text{doPromote}_p() \) at most once during \( \text{release}_p() \).

Claim D.13. Consider \( p \)'s \( k \)-th passage, where \( k \in \mathbb{N} \). Let \( t \) be a point in time at which either \( p \) is poised to execute \( \text{release}_p(j) \), or \( t \in \{ \not\in, \not\in, \not\in, \not\in, \not\in, \not\in, \not\in, \not\in \} \). Then

(a) none of \( p \)'s cease-release events have occurred before time \( t \), and

(b) \( p \) is a releaser of \( \text{lock}_p \) at time \( t \).

Proof. Proof of (a): First note that if \( t \in \{ \not\in, \not\in, \not\in, \not\in \} \) then \( p \) is executing \( \text{doCollect}() \). From Claim D.8(a), \( p \) calls \( \text{doCollect}() \) only in lines 39 and 38. Then if \( t \in \{ \not\in, \not\in \} \) then \( t \in \{ \not\in, \not\in \} \) or \( t \in \{ \not\in, \not\in \} \). Therefore, assume now \( t \in \{ \not\in, \not\in \} \). Then, \( t \in \{ \not\in, \not\in \} \). Then \( p \) is executing \( \text{doCollect}() \) and \( p \) did not execute a call to \( \text{doPromote}_p() \) or \( \text{helpRelease}_p() \) before time \( t \). If \( t \in \{ \not\in, \not\in \} \) then \( p \) is executing \( \text{release}_p() \), and then from a code inspection and Claim D.12(a), it follows that \( p \) did not execute a call to \( \text{doPromote}_p() \) or \( \text{helpRelease}_p() \) before
time \( t \). Then from Claims \( D.8[3] \) and \( D.8[4] \) it follows that events \( \tau_p, \pi_p \) and \( \theta_p \) did not occur before time \( t \). Since \( t \in [\frac{26}{p}, \frac{29}{p}] \) or \( t \in [\frac{37}{p}, \frac{48}{p}] \), it follows from Claim \( D.10 \) that cease-release event \( \phi_p \) did not occur before time \( t \).

**Case b -** \( t \in \{ \frac{50}{p}, \frac{67}{p}, \frac{68}{p} \} \): Then \( p \) is executing \( \text{helpRelease}_p() \). Then from Claim \( D.8[13] \) it follows that \( p \) is executing a call to \( \text{helpRelease}_p() \) in line \( 38 \) or \( 39 \). Then from Claim \( D.10 \) it follows that cease-release event \( \phi_p \) did not occur before time \( t \). From Claim \( D.12[13] \), it follows that this is \( p \)'s only call to \( \text{helpRelease}_p() \). From Claim \( D.8[6] \), \( p \) calls \( \text{doPromote}_p() \) only in line \( 46 \) and in line \( 62 \) (during \( \text{helpRelease}_p() \)). Since \( p \) has not yet executed line \( 46 \) and this is the only call to \( \text{helpRelease}_p() \), \( p \) has not called \( \text{doPromote}_p() \) before time \( t \). Then from Claim \( D.8[1] \) it follows that events \( \pi_p \) and \( \theta_p \) did not occur before time \( t \). By definition, cease-release event \( \tau_p \) occurs when \( p \) executes a successful Sync2.CAS(\( \bot, p \)) in line \( 50 \). If \( t = \frac{50}{p} \), then clearly cease-release event \( \tau_p \) did not occur before time \( t \). If \( t \in [\frac{57}{p}, \frac{62}{p}] \), then \( p \) satisfied the if-condition of line \( 56 \) and thus \( p \) executed an unsuccessful Sync2.CAS(\( \bot, p \)) operation in line \( 50 \) and thus cease-release event \( \tau_p \) did not occur before time \( t \).

**Case c -** \( t \in \{ \frac{65}{p}, \frac{67}{p}, \frac{68}{p} \} \): Then \( p \) is executing \( \text{doPromote}_p() \). From Claim \( D.12[13] \), it follows that this is the only call to \( \text{doPromote}_p() \). By definition, cease-release event \( \theta_p \) occurs only when \( p \) executes a Ctr.CAS(2, 0) operation in line \( 65 \) of \( \text{doPromote}_p() \). Event \( \theta_p \) did not occur before time \( t \) since \( t < \frac{65}{p} \) and this is \( p \)'s only call to \( \text{doPromote}_p() \). By definition, cease-release event \( \pi_p \) occurs only when \( p \) executes a PawnSet.promote() operation that returns a non-\( (\bot, \bot) \) value in line \( 65 \) of \( \text{doPromote}_p() \). If \( t < \frac{65}{p} \), then cease-release event \( \pi_p \) did not occur before time \( t \) since \( \frac{65}{p} < \frac{65}{p} \) (and since \( p \)'s only call to \( \text{doPromote}_p() \)). If \( t \in [\frac{67}{p}, \frac{68}{p}] \), then \( p \) satisfied the if-condition of line \( 65 \) and thus \( p \)'s PawnSet.promote() operation returned value \( (\bot, \bot) \), and thus cease-release event \( \pi_p \) did not occur before time \( t \). Since \( p \) calls \( \text{doPromote}_p() \) only in line \( 46 \) and line \( 62 \) (during \( \text{helpRelease}_p() \)), \( p \) is executing line \( 46 \) or \( 62 \). Then from Claim \( D.10 \) it follows that cease-release event \( \phi_p \) did not occur before time \( t \).

We now show that cease-release event \( \tau_p \) did not occur before time \( t \) thus completing the proof.

**Subcase c(i) -** \( p \) called \( \text{doPromote}_p() \) during \( \text{helpRelease}_p() \): Then \( p \) satisfied the if-condition of line \( 56 \) and thus \( p \) executed an unsuccessful Sync2.CAS(\( \bot, p \)) operation in line \( 50 \) and cease-release event \( \tau_p \) did not occur before time \( t \).

**Subcase c(ii) -** \( p \) called \( \text{doPromote}_p() \) in line \( 46 \) From Claim \( D.11[16] \) \( \text{Role}[p] \in \text{PAWN}_P \) at \( \frac{46}{p} \). Since \( \text{Role}[p] \) is unchanged during \( \text{release}_p() \) (Claim \( D.4[11] \)), it follows that \( \text{Role}[p] = \text{PAWN}_P \) at \( \frac{46}{p} \) and \( \frac{42}{p} \). Then \( p \) fails the if-conditions of lines \( 35 \) and \( 12 \) and does not execute a call to \( \text{helpRelease}_p() \) before time \( t \). Then from Claim \( D.8[6] \) it follows that cease-release event \( \tau_p \) did not occur before time \( t \).

**Proof of (b):** From Part (a), \( p \) does not cease to be releaser of \( L \) before \( t \). Therefore, to prove our claim we need to show that \( p \) becomes a releaser of \( L \) at some point \( t' < t \). We first show that \( \text{Role}[p] \in \{ \text{KING}, \text{QUEEN}, \text{PAWN}_P \} \) at time \( t \). Let \( t' \) be the point when \( p \) is poised to execute \( \text{release}_p(j) \). From the inspection of the various points in time chosen for \( t \) (including \( \frac{34}{p} \), but excluding \( t' \)) and the table in Claim \( D.11 \) it follows that \( \text{Role}[p] \in \{ \text{KING}, \text{QUEEN}, \text{PAWN}_P \} \) at time \( t \) (including \( \frac{34}{p} \), but excluding \( t' \)). Clearly \( \text{Role}[p] \) is unchanged during \( \frac{t' \div 1}{p} \). Then the value of \( \text{Role}[p] \) at \( t' \) is the same as that at \( \frac{31}{p} \), i.e., \( \text{Role}[p] \in \{ \text{KING}, \text{QUEEN}, \text{PAWN}_P \} \).

**Case a -** \( \text{Role}[p] \in \{ \text{KING}, \text{QUEEN} \} \) at time \( t \): From Claim \( D.4[11] \), \( \text{Role}[p] \) is set to \( \text{KING} \) or \( \text{QUEEN} \) only when \( p \) executes line \( 5 \). Then \( p \) changed \( \text{Role}[p] \) to \( \text{KING} \) or \( \text{QUEEN} \) at \( \frac{5}{p} \), and thus \( p \) became a releaser of lock \( L \) by condition (R1) at \( \frac{5}{p} \) = \( t' \) < \( t \).

**Case b -** \( \text{Role}[p] = \text{PAWN}_P \) at time \( t \): From Claim \( D.9 \) it follows that some process \( q \)
promoted \( p \) at \( \frac{65}{q} \) and \( p \) became a releaser of \( L \) by condition (R2) at \( \frac{65}{q} = t' < t \). \( \square \)

Claim D.14. Consider \( p \)'s \( k \)-th passage, where \( k \in \mathbb{N} \). If any of process \( p \)'s cease-release events occurs at time \( t \) then \( p \) ceases to be the releaser of lock \( L \) at time \( t \).

Proof. To prove our claim we need to show that \( p \) is a releaser of \( L \) immediately before time \( t \), since by definition \( p \) ceases to be a releaser of \( L \) when any of \( p \)'s cease-release events occurs. By definition, cease-release event \( \phi_p \) occurs when \( p \) executes a successful \( \text{Ctr.CAS}(1,0) \) operation in line 36 cease-release event \( \pi_p \) occurs when \( p \) executes a successful \( \text{Sync2.CAS}(\bot, p) \) in line 56 cease-release event \( \theta_p \) occurs only when \( p \) executes a \text{PawnSet.promote()} operation that returns a non-\( \langle \bot, \bot \rangle \) value in line 55 cease-release event \( \tau_p \) occurs only when \( p \) executes a \( \text{Ctr.CAS}(2,0) \) operation in line 68.

From Claim D.13(b), \( p \) is a releaser of \( L \) at \( \frac{36}{p} \), \( \frac{56}{p} \), \( \frac{65}{p} \), and \( \frac{68}{p} \). Hence, the claim follows. \( \square \)

We say a process has write-access to objects \( \text{Sync1} \) and \( \text{Sync2} \), respectively, if the process can write a value to \( \text{Sync1} \) and \( \text{Sync2} \), respectively. We say a process has registration-access to object \( \text{PawnSet} \), if the process can execute an operation on \( \text{PawnSet} \) that can write values in \( \langle a, b | a \in \{0, 1, 2\} = \{0, \text{REG}, \text{PRO}\}, b \in \mathbb{N} \rangle \) to some entry of \( \text{PawnSet} \). We say a process has deregistration-access to object \( \text{PawnSet} \), if the process can execute an operation on \( \text{PawnSet} \) that can write value \( \langle \text{ABORT}, s \rangle = \langle 3, s \rangle \), where \( s \in \mathbb{N} \), to some entry of \( \text{PawnSet} \). Object \( \text{PawnSet} \) is said to be candidate-empty if no entry of \( \text{PawnSet} \) has value \( \langle \text{REG}, \_ \rangle \) or \( \langle \text{PRO}, \_ \rangle \).

Claim D.15. Only releasers of \( L \) have write-access to \( \text{Sync1} \), \( \text{Sync2} \) and registration-access to \( \text{PawnSet} \).

Proof. The following observations follow from an inspection of the code. A value can be written to \( \text{Sync1} \) only in lines 26, 37 and 58. A value can be written to \( \text{Sync2} \) only in lines 56 and 60. From the semantics of the \( \text{AbortableProArray}_a \) object, only operations \( \text{collect()}, \text{promote()} \), and \( \text{reset()} \) can write values in \( \langle a, b | a \in \{0, \text{REG}, \text{PRO}\} = \{0, 1, 2\}, b \in \mathbb{N} \rangle \) to \( \text{PawnSet} \). From Claim D.13(i), the operations \( \text{collect()}, \text{promote()} \), and \( \text{reset()} \) are executed on \( \text{PawnSet} \) only in lines 55 and 67, respectively.

Suppose an arbitrary process \( p \) writes a value to \( \text{Sync1} \) or \( \text{Sync2} \), or a value in \( \langle a, b | a \in \{0, 1, 2\}, b \in \mathbb{N} \rangle \) to an entry of \( \text{PawnSet} \). From Claim D.13(b), \( p \) is a releaser of \( L \) at \( \frac{26}{p} \), \( \frac{37}{p} \), \( \frac{55}{p} \), \( \frac{56}{p} \), \( \frac{60}{p} \), \( \frac{65}{p} \), \( \frac{67}{p} \), and \( \frac{55}{p} \). Hence, the claim follows. \( \square \)

Claim D.16. The \( i \)-entry of \( \text{PawnSet} \) can be changed only by process \( i \) or a releaser of \( L \).

Proof. The values that can be written to \( \text{PawnSet} \) are in \( \langle a, b | a \in \{0, 1, 2, 3\}, b \in \mathbb{N} \rangle \). A process that can write values in \( \langle a, b | a \in \{0, 1, 2\}, b \in \mathbb{N} \rangle \) to any entry of \( \text{PawnSet} \) is said to have registration-access to \( \text{PawnSet} \). From Claim D.15 it follows that only a releaser of \( L \) has registration-access to \( \text{PawnSet} \), therefore only a releaser of \( L \) can write values in \( \langle a, b | a \in \{0, 1, 2\}, b \in \mathbb{N} \rangle \) to the \( i \)-th entry of \( \text{PawnSet} \). From Claim D.13(i) the value \( \langle \text{ABORT}, s \rangle = \langle 3, s \rangle \), where \( s \in \mathbb{N} \), can be written to the \( i \)-th entry of \( \text{PawnSet} \) only when a process executes a \( \text{remove}(i) \), \( \text{remove}(i) \) or \( \text{PawnSet.abort}(i, s) \) operation in line 64 or 61 respectively. From Claim D.13(b), it follows that a process executing lines 64 and 61 is a releaser of \( L \). Since a \( \text{PawnSet.abort}(i, s) \) operation in line 21 is executed only by process \( i \), our claim follows. \( \square \)

Claim D.17. \( \text{Sync2} \) is changed to a non-\( \bot \) value only by a releaser of \( L \) (say \( r \)) in line 36 which triggers the cease-release event \( \tau_r \).
Proof. By definition, cease-release event \( \tau_p \) occurs when \( p \) executes a successful \( \text{Sync2.CAS}(\bot, p) \) in line 55. From a code inspection, \( \text{Sync2} \) is changed to a non-\( \bot \) value only when some process (say \( r \)) executes a successful \( \text{Sync2.CAS}(\bot, r) \) operation in line 56. From Claim \( \text{D.15} \) it follows that \( \text{Sync2} \) is changed only by a releaser of \( L \). Then \( r \) is a releaser of \( L \) when it changes \( \text{Sync2} \) to a non-\( \bot \) value in line 56 and doing so triggers the cease-release event \( \tau_r \).

Claim D.18. A \( \text{PawnSet.promote}() \) operation is executed only by a releaser of \( L \) (say \( r \)), and if the value returned is non-\( \langle \bot, \bot \rangle \) the cease-release event \( \pi_r \) is triggered.

Proof. By definition, cease-release event \( \pi_p \) occurs only when \( p \) executes a \( \text{PawnSet.promote}() \) operation that returns a non-\( \langle \bot, \bot \rangle \) value in line 65. From a code inspection, a \( \text{PawnSet.promote}() \) operation is executed only when some process (say \( r \)) executes line 56. From Claim \( \text{D.15} \) it follows that \( \text{PawnSet} \) is changed only by a releaser of \( L \). Then \( r \) is a releaser of \( L \) when it executes a \( \text{PawnSet.promote}() \) operation, and if the operation returns a non-\( \langle \bot, \bot \rangle \) value then the cease-release event \( \pi_r \) is triggered.

Claim D.19. During an execution of \( \text{doPromote}_p() \) exactly one of the events \( \pi_p \) and \( \theta_p \) occurs.

Proof. By definition, cease-release event \( \pi_p \) occurs when \( p \) executes a \( \text{PawnSet.promote}() \) operation in line 65 that returns a non-\( \langle \bot, \bot \rangle \) value, and cease-release event \( \theta_p \) occurs when \( p \) executes a \( \text{Ctr.CAS}(2, 0) \) operation in line 68 during \( \text{doPromote}_p() \).

Case a - the \( \text{PawnSet.promote}() \) operation in line 65 returns a non-\( \langle \bot, \bot \rangle \) value, and thus cease-release event \( \pi_p \) occurs: Then \( p \) fails the if-condition of line 66 and line 68 is not executed. Therefore, cease-release event \( \theta_p \) does not occur.

Case b - the \( \text{PawnSet.promote}() \) operation in line 65 returns \( \langle \bot, \bot \rangle \), and thus cease-release event \( \pi_p \) does not occur: Then \( p \) satisfies the if-condition of line 66 and executes a \( \text{Ctr.CAS}(2, 0) \) operation in line 68. Hence, cease-release event \( \theta_p \) occurs.

Claim D.20. During an execution of \( \text{helpRelease}_p() \) exactly one of the events \( \tau_p, \pi_p \) and \( \theta_p \) occurs.

Proof. By Claim \( \text{D.7} \) events \( \pi_p \) and \( \theta_p \) can only occur during \( p \)'s call to \( \text{doPromote}_p() \), and cease-release event \( \tau_p \) occurs when \( p \) executes a successful \( \text{Sync2.CAS}(\bot, p) \) operation in line 56.

Case a - \( p \) executes a successful \( \text{Sync2.CAS}(\bot, p) \) operation in line 56 and thus cease-release event \( \tau_p \) occurs: Then \( p \) fails the if-condition of line 56 and returns immediately from its call to \( \text{helpRelease}_p() \). Therefore, events \( \pi_p \) and \( \theta_p \) do not occur.

Case b - \( p \) executes an unsuccessful \( \text{Sync2.CAS}(\bot, p) \) operation in line 56 and thus cease-release event \( \tau_p \) does not occur. Then \( p \) satisfies the if-condition of line 56 and calls \( \text{doPromote}_p() \) in line 62. From Claim \( \text{D.19} \) exactly one of the events \( \pi_p \) and \( \theta_p \) occurs during \( p \)'s call to \( \text{doPromote}_p() \).

Claim D.21. The value of \( \text{Ctr} \) can change only when a \( \text{Ctr.inc}() \), \( \text{Ctr.CAS}(2, 0) \) or \( \text{Ctr.CAS}(1, 0) \) operation is executed in lines 34, 68 or 77.

Proof. From the semantics of the RCASCounter2 object, if \( \text{Ctr} \) is increased to value \( i \) by a \( \text{Ctr.inc}() \) operation, then its value was \( i - 1 \) immediately before the operation was executed. Then all claims follow from an inspection of the code.

Claim D.22. If the value of \( \text{Ctr} \) changes, it either increases by 1 or decreases to 0. Moreover its values are in \( \{0, 1, 2\} \).
Proof. From the semantics of the RCAScounter2 object, a \texttt{Ctr.inc()} operation changes the value of \texttt{Ctr} from \(i\) to \(i+1\) only if \(i \in \{0, 1\}\). From Claims [D.21] the value of \texttt{Ctr} can change only when a \texttt{Ctr.inc()}, \texttt{Ctr.CAS}(2, 0) or \texttt{Ctr.CAS}(1, 0) operation is executed (in lines 5, 38 or 39). Then it follows that the values of \texttt{Ctr} are in\{0, 1, 2\}. It also follows that the value of \texttt{Ctr} either changes from 0 to 1 and back to 0, or it changes from 0 to 1 and back to 0.

\textbf{Ctr-Cycle Interval} \(T\). Let \(T = [t_s, t_e]\) be a time interval where \(t_s\) is a point when \texttt{Ctr} is 0 and \(t_e\) is the next point in time when \texttt{Ctr} is decreased to 0. For \(i \in \{0, 1, 2\}\) let \(I_i = \{t \in T | \text{Ctr} = i\} \) and let time \(I^-_i = \min(I_i)\) and time \(I^+_i = \max(I_i)\). From Claim [D.22] it follows immediately that during \(T\) the set \(I_i, i \in \{0, 1, 2\}\), forms an interval \([I^-_1, I^+_1]\), and \(I_2 = \emptyset\) if and only if \texttt{Ctr} is never increased to 2 during \(T\). Moreover, \(t_s = I^-_0\) and \(I_0\) is immediately followed by \(I_1\) (i.e., \(\min(I_1) = \max(I_0) + 1\)). If \(I_2 \neq \emptyset\) then \(I_2\) follows immediately after \(I_1\). The \texttt{Ctr}-cycle interval \(T\) ends either at time \(I^+_1\) if \(I_2 = \emptyset\), or at time \(I^+_2\) if \(I_2 \neq \emptyset\).

Then it also follows that exactly one process changes \texttt{Ctr} from 0 to 1 during \(T\), and it does so at time \(I^-_1\). Let \(K\) be the process that increases \texttt{Ctr} to 1 at time \(I^-_1\). And if \(I_2 \neq \emptyset\) then exactly one process changes \texttt{Ctr} from 1 to 2 during \(T\), and it does so at time \(I^-_2\). If \(I_2 \neq \emptyset\) let \(Q\) be the process that increases \texttt{Ctr} to 2 at time \(I^-_2\). Let \(R(t)\) denote the set of processes that are the releasers of \texttt{lock L} at time \(t \in T\).

\textbf{Claim D.23.} If \(R(I^-_0) = \emptyset\) and at \(I^-_0\), \(\text{Sync}1 = \text{Sync}2 = \bot\) and \(\text{PawnSet}\) is candidate-empty, then the following holds:

(a) \(\forall \tau \in I_0 : R(\tau) = \emptyset\) and throughout \(I_0\), \(\text{Sync}1 = \text{Sync}2 = \bot\) and \(\text{PawnSet}\) is candidate-empty.

(b) \(\{K\} = R(I^-_1) \) and at time \(I^-_1\), \(\text{Sync}1 = \text{Sync}2 = \bot\) and \(\text{PawnSet}\) is candidate-empty.

(c) \(K\) executes lines of code of \texttt{lockK()} starting with line 2 as depicted in Figure 8. (A legend for the figure is given in Figure 7.)

\[\text{Apply}[K].\text{CAS}((\bot, 1), (\text{REG}, s))\]

\[\begin{array}{c}
\text{false} \\
\text{true}
\end{array}\]

\[\text{Role}[K] = \text{KING} = 0\]

\[\text{K returns } \infty\]

\[5 \quad 6 \quad 12 \quad 13 \quad 16 \quad 17\]

\text{Figure 8: } K\text{’s call to } \text{lockK()}\

(d) \(K\text{’s call to } \text{lockK()} \) returns \(\infty\) and \text{Role}[K] = \text{KING} throughout \([K, K^-]\).

(e) \(K\) executes a \texttt{Ctr.CAS}(1, 0) operation in line 39 during \(T\), and \(K\) does not change \text{Sync}1, \text{Sync}2 or \text{PawnSet} throughout \([I^-_1, I^-_2]\).

(f) \(\forall \tau \in I_1 : R(\tau) = \{K\}\).

(g) Throughout \(I_1\), \(\text{Sync}1 = \text{Sync}2 = \bot\) and \text{PawnSet} is candidate-empty.

\textbf{Proof. Proof of (a)}: Consider the claim \(R(\tau) = \emptyset\) where \(\tau \in I_0\). Since \(R(I^-_0) = \emptyset\) holds by assumption, the claim holds at \(\tau = I^-_0\). For the purpose of a contradiction assume the claim fails to hold for the first time at some point \(\tau'\) during \(I_0\). Then some process \(p\) becomes a releaser of
lock \( L \) at time \( t' \). Process \( p \) cannot become a releaser of \( L \) by \( p \) increasing \( Ctr \) to 1 or 2 (condition (R1)) at time \( t' \), since \( Ctr = 0 \) throughout \( I_0 \). Therefore, assume it becomes a releaser of \( L \) when some process \( q \) promotes \( p \) (condition (R2)) at \( t' \). By Claim \( \text{D.14} \) \( q \) ceases to be a releaser of lock \( L \) at \( t' \). This is a contradiction to our assumption that \( p \) is the first process during \( I_0 \) to become a releaser of \( L \).

By assumption the variables \( \text{Sync1}, \text{Sync2} \) and \( \text{PawnSet} \) are at their initial value at \( I_0^0 \). Since the values of these variables are only changed by a releaser of lock \( L \) (by Claim \( \text{D.15} \)) and for all \( t \in I_0 \), \( R(t) = \emptyset \), it follows that the variables are unchanged throughout \( I_0 \).

Proof of (b): At time \( I_1^- \) \( Ctr \) is increased from 0 to 1, and thus the only operation executed is a \( \text{Ctri}.\text{inc}() \) operation by process \( \mathcal{K} \). Then \( \mathcal{K} \) becomes a releaser of lock \( L \) at time \( I_1^- \) by condition (R1). Since for all \( t \in I_0 \), \( R(t) = \emptyset \) (Part (a)), it follows that \( R(I_1^-) = \{ \mathcal{K} \} \). Since \( \text{Sync1} = \text{Sync2} = \perp \) and \( \text{PawnSet} \) is candidate-empty throughout \( I_0 \) (Part (a)), the only operation at time \( I_1^- \) is the \( \text{Ctri}.\text{inc}() \) operation, it follows that \( \text{Sync1} = \text{Sync2} = \perp \) and \( \text{PawnSet} \) is candidate-empty at time \( I_1^- \).

Proof of (c) and (d): Since \( \mathcal{K} \) is the process that increased \( Ctr \) from 0 to 1 at time \( I_1^- \), and since \( \mathcal{K} \) can increase \( Ctr \) only by executing a \( \text{Ctri}.\text{inc}() \) operation in line 5 (by Claim \( \text{D.21} \)) \( \mathcal{K} \) set \( \text{Role}[\mathcal{K}] = 0 = \text{KING} \) at \( t_5^- \). Then from the code structure, \( \mathcal{K} \) does not execute lines 7-9 and does not repeat the role-loop, and does not busy-wait in the spin loop of line 14 instead \( \mathcal{K} \) proceeds to execute lines 16-17 and returns value \( \infty \) in line 17. Since \( \mathcal{K} \) does not change \( \text{Role}[\mathcal{K}] \) during \( [t_5^- t_7^+] \), \( \text{Role}[\mathcal{K}] = \text{KING} \) throughout \( [t_5^- t_7^+] \).

Proof of (e): Since \( \mathcal{K} \) is the process that increased \( Ctr \) from 0 to 1 at time \( I_1^- \), and since \( \mathcal{K} \) can increase \( Ctr \) only by executing a \( \text{Ctri}.\text{inc}() \) operation in line 5 (by Claim \( \text{D.21} \)) \( \mathcal{K} \) set \( \text{Role}[\mathcal{K}] = 0 = \text{KING} \) at \( t_5^- \). From Part (a), \( \mathcal{K} \) returns from \( \text{lock}() \) with value \( \infty \) in line 17 and thus \( \mathcal{K} \) consequently calls \( \text{release}(j) \) (follows from conditions (b) and (d)). Note that \( \mathcal{K} \) has not executed any operations on \( \text{Sync1}, \text{Sync2} \) and \( \text{PawnSet} \) in the process. Then \( \text{Role}[\mathcal{K}] = \text{KING} \) at \( t_5^- \), and thus \( \mathcal{K} \) executes the \( \text{Ctri}.\text{CAS}(1,0) \) operation in line 36 during \( T \) without having executed any operations on \( \text{Sync1}, \text{Sync2} \) and \( \text{PawnSet} \) in the process. Thus \( \mathcal{K} \) did not change \( \text{Sync1}, \text{Sync2} \) or \( \text{PawnSet} \) during \( [I_1^-, t_{36}^-] \).

Proof of (f): Since \( R(I_1^-) = \{ \mathcal{K} \} \) (Part (b)), to prove our claim we need to show that during \( I_1 \) \( \mathcal{K} \) does not cease to be a releaser and no process becomes a releaser. Suppose not, i.e., the claim \( R(t) = \{ \mathcal{K} \} \) fails to hold for the first time at some point \( t' \) in \( I_1 \).

Case a - Process \( \mathcal{K} \) ceases to be a releaser of \( L \) at \( t' \): By definition, cease-release event \( \phi_{\mathcal{K}} \) occurs when \( \mathcal{K} \) executes a successful \( \text{Ctri}.\text{CAS}(1,0) \) operation in line 36. From Part (c), \( \mathcal{K} \) executes a \( \text{Ctri}.\text{CAS}(1,0) \) operation in line 36. If \( \mathcal{K} \) executes a successful \( \text{Ctri}.\text{CAS}(1,0) \) operation in line 36 then, by definition, cease-release event \( \phi_{\mathcal{K}} \) occurs and by Claim \( \text{D.14} \) \( \mathcal{K} \) ceases to be the releaser of \( L \). Thus, \( t' = t_{36}^- \) and \( Ctr \) changes to value \( 0 \) at \( t' \). But since \( t' \in I_1 \) and \( Ctr = 1 \) throughout \( I_1 \), we have a contradiction. If \( \mathcal{K} \) executes an unsuccessful \( \text{Ctri}.\text{CAS}(1,0) \) operation in line 36 then \( Ctr \neq 1 \) at \( t_{36}^- \). Since \( p \) did not cease to a releaser at \( t_{36}^- \), \( t_{36}^- < t' \). Since \( I_1^- = [t_5^- t_{36}^-] < t' < I_1^+ \) and \( Ctr = 1 \) throughout \( I_1 \), and thus we have a contradiction.

Case b - Some process \( q \) becomes a releaser of \( L \) at \( t' \): Since \( Ctr \) is not increased during \( I_1 \), it follows from conditions (R1) and (R2) that some process \( r \) promoted \( q \) at time \( t' \). Then by definition, event \( \pi_r \) occurs at \( t' \), and thus from Claim \( \text{D.14} \) it follows that \( r \) is a releaser of \( L \) immediately before \( t' \). Since \( \mathcal{K} \) is the only releaser immediately before \( t' \), \( r = \mathcal{K} \). Then cease-release event \( \pi_{\mathcal{K}} \) occurred at \( t' \) and \( \mathcal{K} \) ceases to be a releaser at \( t' \). As was shown in Case a, this leads to a contradiction.

Proof of (g): At time \( I_1^- \) the claim \( \text{Sync1} = \text{Sync2} = \perp \) and \( \text{PawnSet} \) is candidate-empty holds by Part (b). Suppose some process \( p \) changes \( \text{Sync2} \) or \( \text{Sync1} \) or \( \text{PawnSet} \) for the first time
at some point $t'$ during $I_1$. From Claim [D.15] it follows that $p$ is a releaser of lock $L$ at time $t'$. Since for all $t \in I_1$, $R(t) = \{K\}$ (Part [f]), it follows that $p = K$. From Part [g], $K$ does not change any of the variables before the point when it executes a $\text{Ctr.CAS}(1,0)$ operation in line 36, i.e., $\frac{36}{K} < t'$. If $K$ executes a successful $\text{Ctr.CAS}(1,0)$ operation in line 36 then the interval $I_1$ ends and clearly $t' \notin I_1$, hence a contradiction. If $K$ executes an unsuccessful $\text{Ctr.CAS}(1,0)$ operation in line 36 then $\text{Ctr} \neq 1$ at $\frac{36}{K}$. Since $I_{-2} = \frac{36}{K} < I_1 < I_1' < I_2$ and $\text{Ctr} = 1$ throughout $I_1$, we have a contradiction. 

Claim D.24. If $I_2 \neq \emptyset$ and $R(I_-2) = \emptyset$ and at $I_0$, $\text{Sync1} = \text{Sync2} = \bot$ and PawnSet is candidate-empty, then the following claims hold:

(a) $R(I_-2) = \{K, Q\}$ and at time $I_2$, $\text{Sync1} = \text{Sync2} = \bot$ and PawnSet is candidate-empty.

(b) $K$ and $Q$ are the first two releasers of $L$.

(c) During $(I_2, I_2^+]$ a process can become a releaser of $L$ only if it gets promoted by a releaser of $L$.

(d) If $K$ takes enough steps, $K$ executes lines of code of $\text{release}_K()$ starting with line 34 as depicted in Figure 9.

(e) $K$ executes an unsuccessful $\text{Ctr.CAS}(1,0)$ operation in line 36 and calls $\text{helpRelease}_K()$ in line 39 such that $I_2 < \frac{36}{K} < \frac{39}{K}$.

(f) If $K$ and $Q$ take enough steps, $Q$ finishes $\text{lock}_Q()$ during $T$.

(g) If $K$ and $Q$ take enough steps, $Q$ executes lines of code of $\text{lock}_Q()$ starting with line 2 as depicted in Figure 10.

(h) If $Q$ calls $\text{release}_Q()$, it executes lines of code of $\text{release}_Q()$ starting with line 34 as depicted in Figure 11.

(i) $Q$ calls $\text{helpRelease}_Q()$ either in line 30 or in line 43 after time $I_2$.

Figure 9: $K$’s call to $\text{release}_K(j)$

**Proof.** Proof of (a) and (b): Since $Q$ is the process that increases $\text{Ctr}$ from 1 to 2 at time $I_2$, and since $Q$ can increase $\text{Ctr}$ only by executing a $\text{Ctr.inc()}$ operation in line 5 (by Claim [D.21]) $Q$ becomes a releaser of lock $L$ by condition (R1) at $I_2 = \frac{5}{Q}$. Since for all $t \in I_1$, $R(t) = \{K\}$
(Claim D.23(f)), it follows that \( R(I_2^-) = \{K, Q\} \). By claim D.23(g), throughout \( I_1 \), Sync1 = Sync2 = \( \perp \) and PawnSet is candidate-empty, and since the only operation executed at time \( I_2^- \) is Ctr.inc(), it follows that at time \( I_2^- \), Sync1 = Sync2 = \( \perp \) and PawnSet is candidate-empty. Hence Part (b) holds. Clearly \( K \) and \( Q \) are the first two releasers of \( L \), hence Part (b) holds.

Proof of (c): From conditions (R1) and (R2), a process can become a release r of \( L \) either by increasing \( Ctr \) to 1 or 2 or by getting promoted. Since \( Ctr \) is not increased during \( (I_2^-, I_2^+) \), it follows that during \( (I_2^-, I_2^+) \) a process becomes a releaser of \( L \) only if it gets promoted. By definition, a process can be promoted only when a PawnSet.promote() operation is executed in line 65 and from Claim D.18 only a releaser of \( L \) can execute this operation. Then during \( (I_2^-, I_2^+) \) a process becomes a releaser of \( L \) only if it gets promoted by a releaser of \( L \).

Proof of (d) and (e): From Claim D.23(e), \( K \) executes the Ctr.CAS(1,0) operation in line 36 during \( T \). If \( K \)'s Ctr.CAS(1,0) operation is successful then the value of \( Ctr \) decreases from 1 to 0 and the Ctr-cycle interval \( T \) ends and thus \( I_2 = \emptyset \), which is a contradiction to our assumption that \( I_2^- \neq \emptyset \). Then \( K \)'s Ctr.CAS(1,0) operation is unsuccessful.

Since \( K \) executes an unsuccessful Ctr.CAS(1,0) operation in line 36 \( K \) satisfies the if-condition of line 36 executes lines 37-38 and calls helpRelease\(_{K}() \) in line 39 and then executes lines 49-50.

Since \( K \) executes an unsuccessful Ctr.CAS(1,0) operation in line 36 it follows that \( Ctr \) was changed from 1 to 2 at time \( I_2^- \) (by definition), and thus \( I_2^- < t_{K}^{36} \). Since \( t_{K}^{36} < t_{K}^{39} \), it follows that \( I_2^- < t_{K}^{36} < t_{K}^{39} \).

Proof of (f), (g) and (h): Since \( Q \) is the process that increases \( Ctr \) from 1 to 2 at time \( I_2^- \), and since \( Q \) can increase \( Ctr \) only by executing a Ctr.inc() operation in line 5 (by Claim D.21) \( Q \) set Role[\( K \)] = 1 = QUEEN at \( t_{Q}^{5} = I_2^- \). Then from the code structure, \( Q \) does not execute lines 7-9 and does not repeat the role-loop, instead, it proceeds to line 13 and then proceeds to busy-wait in the spin loop of line 14. Then \( Q \) does not finish lock\(_{Q}() \) only if it spins indefinitely in line 14 and does not receive a signal to abort.

For the purpose of a contradiction assume that \( Q \) does not finish lock\(_{Q}() \). Then \( Q \) reads the
value ⊥ from Sync1 in line 14 indefinitely. From Part (iii) it follows that \( \mathcal{K} \) executes a \( \text{Sync1.CAS}(\perp, j) \) operation in line 27 during \((I^-_2, I^+_2)\). Since Sync1 = \( \perp \) at time \( I^-_2 \) (Part (iii)), and only a releaser can change Sync1 (Claim D.15), and \( Q \) is busy-waiting in line 14, it follows that the only other releaser, \( \mathcal{K} \), executed a successful \( \text{Sync1.CAS}(\perp, \mathcal{K}) \) operation in line 27 during \((I^-_2, I^+_2)\) and changed Sync1 to a non-⊥ value. Then for \( Q \) to read \( \perp \) from Sync1 in line 14 indefinitely, some process must reset Sync1 to \( \perp \) before \( Q \) reads Sync1 again.

**Case a** - \( \mathcal{K} \) resets Sync1 in line 58 before \( Q \) reads Sync1 again: For \( \mathcal{K} \) to reset Sync1 in line 58, \( \mathcal{K} \) must satisfy the if-condition of line 56 and thus \( \mathcal{K} \) must execute an unsuccessful \( \text{Sync2.CAS}(\perp, \mathcal{K}) \) operation in line 56. Since Sync2 = \( \perp \) at time \( I^-_2 \) (Part (iii)), and only a releaser can change Sync2 (Claim D.15), and \( Q \) is busy-waiting in line 14, it follows that Sync2 = \( \perp \) at \( I^-_2 \). Thus \( \mathcal{K} \)'s \( \text{Sync2.CAS}(\perp, \mathcal{K}) \) operation in line 56 is successful and we get a contradiction.

**Case b** - some other process becomes a releaser and resets Sync1 before \( Q \) reads Sync1 again: From Part (iii) it follows that during \((I^-_2, I^+_2)\) a process can become a releaser of \( L \) only if it is promoted (by condition (R2)). Since a process is promoted only by a releaser of \( L \) and \( \mathcal{K} \) is the only other releaser of \( L \) apart from \( Q \), it follows that \( \mathcal{K} \) promotes some process before \( Q \) reads Sync1 again. As argued in Case a, \( \mathcal{K} \) executes a successful \( \text{Sync2.CAS}(\perp, \mathcal{K}) \) operation in line 56. Then from the code structure, \( \mathcal{K} \) does not call \( \text{doPromote}_\mathcal{K}() \) in line 62 and thus \( \mathcal{K} \) does not promote any process. Hence, we have a contradiction.

**Proof of (ii)**: Since \( Q \) is the process that increases \( \text{Ctr} \) from 1 to 2 at time \( I^-_2 \), and since \( Q \) can increase \( \text{Ctr} \) only by executing a \( \text{Ctr.inc()} \) operation in line 5 (by Claim D.21), \( Q \) set \( \text{Role}[\mathcal{K}] = 1 \) = QUEEN at \( I^-_2 \). Then from the code structure, \( Q \) does not execute lines 7-9 and does not repeat the role-loop; instead, it proceeds to line 13 and then proceeds to busy-wait in the spin loop of line 14.

**Case a** - \( Q \) does not receive a signal to abort while busy-waiting in line 14: From Part (ii), \( Q \) does not busy-wait indefinitely in line 14 and eventually breaks out. Since \( Q \) breaks out of the spin loop of line 14 it reads non-⊥ from Sync1 and then from the code structure it follows that \( Q \) goes on to return that non-⊥ value in line 17. Consequently \( Q \) calls \( \text{release}_Q(j) \) (follows from conditions 1 and 4). Consider \( Q \)'s call to \( \text{release}_Q(j) \). Since \( Q \) last changed \( \text{Role}[Q] \) only in line 5 \( \text{Role}[Q] = \text{QUEEN} \) at \( I^-_2 \). Since \( \text{Role}[Q] \) is unchanged during \( \text{release}_Q() \) (Claim D.15), it follows that \( \text{Role}[Q] = \text{QUEEN} \) throughout \( \text{release}_Q() \). Then from the code structure it follows that \( Q \) executes only lines 34-35, 42-45 and 49-50. Then \( Q \) calls \( \text{helpRelease}_Q() \) only in line 43 and since \( I^-_2 = \frac{5}{Q} < \frac{1}{K} \), our claim holds.

**Case b** - \( Q \) receives a signal to abort while busy-waiting in line 14: Then \( Q \) calls \( \text{abort}_Q() \), and from the code structure \( Q \) executes lines 18-20 and then line 26. If \( Q \) fails the \( \text{Sync1.CAS}(\perp, \infty) \) operation of line 26 then Sync1 ≠ \( \perp \) at \( I^-_2 \). From Claim D.15 only a releasers of \( L \) can change Sync1 to a non-⊥ value, and since \( \mathcal{K} \) and \( Q \) are the only releasers of \( L \), it follows that \( \mathcal{K} \) changed Sync1 to a non-⊥ value. Then \( Q \) satisfies the if-condition of line 26 and returns the non-⊥ value written by \( \mathcal{K} \) to Sync1 in line 27. Consequently \( Q \) calls \( \text{release}_Q(j) \) (follows from conditions 1 and 4), and as argued in Case a, \( Q \) executes only lines 34-35, 42-45 and 49-50 and \( Q \) calls \( \text{helpRelease}_Q() \) only in line 43. Since \( I^-_2 = \frac{5}{Q} < \frac{3}{Q} \), our claim holds.

If \( Q \)'s \( \text{Sync1.CAS}(\perp, \infty) \) operation is successful, then \( Q \) goes on to call \( \text{doCollect}_Q() \) in line 26 calls \( \text{helpRelease}_Q() \) in line 30 then executes lines 32-33 and finally returns ⊥ in line 33. Since \( I^-_2 = \frac{5}{Q} < \frac{3}{Q} \), our claim holds.

Define \( \lambda \) to be the first point in time when \( \text{Sync2} \) is changed to a non-⊥ value, and if \( \text{Sync2} \) is never changed to non-⊥ then \( \lambda = \infty \). Define \( \gamma \) to be the first point in time when a \( \text{PawnSet.promote()} \) operation is executed, and if a \( \text{PawnSet.promote()} \) operation is never executed
then $\gamma = \infty$. From Claims D.24(c) and D.24(i), both $K$ and $Q$ execute $\text{helpRelease}_K()$ and $\text{helpRelease}_Q()$, respectively, after time $I_2^-$. Let $A \in \{K, Q\}$ be the first process among them to execute line 56 and let $B \in \{K, Q\} - \{A\}$ be the other process, i.e., $t_A < \underline{t_B}$.

**Claim D.25.** If $I_2^- \not= \emptyset$ and $R(I_2^-) = \emptyset$ and at $I_2^-$, $\text{Sync1} = \text{Sync2} = \bot$ and PawnSet is candidate-empty, then the following claims hold:

(a) $I_2^- < \lambda = \underline{t_A}^-$ and for all $t \in [I_2^-, \lambda)$, $R(t) = \{K, Q\}$ and $\text{Sync2} = \bot$ throughout $[I_2^-, \lambda)$, and cease-release event $\tau_A$ occurs at $\lambda$.

(b) If $K$ and $Q$ take enough steps, then $A$ executes lines of code of $\text{helpRelease}_A()$ starting with line 56 as depicted in Figure 12.

(c) If $K$ and $Q$ take enough steps, then $B$ executes lines of code of $\text{helpRelease}_B()$ and $\text{doPromote}_B()$ as depicted in Figures 13 and 14, respectively.

(d) $\lambda < \gamma = \underline{t_B}$.

(e) $\forall t \in [\lambda, \gamma)$, $R(t) = \{B\}$.

(f) At time $\gamma$, $\text{Sync1} = \text{Sync2} = \bot$.

(g) No promotion event occurs at lock $L$ during $[I_2^-, \gamma)$.
(h) The \texttt{PawnSet.promote()} operation at time $\gamma$ does not return a value in $
abla(a, b) | a \in \{K, Q\}, b \in \mathbb{N}$.

(i) If the \texttt{PawnSet.promote()} operation at time $\gamma$ returns a non-$\{\bot, \bot\}$ value then $\mathcal{B}$'s cease-release event $\theta_\mathcal{B}$ occurs at time $\gamma$.

(j) If the \texttt{PawnSet.promote()} operation at time $\gamma$ returns value $\langle \bot, \bot \rangle$ then $\mathcal{B}$'s cease-release event $\theta_\mathcal{B}$ occurs at $t' = t_\mathcal{B} + \lambda \geq \gamma$, and throughout $[\gamma, t')$ no process is promoted, and $\forall t \in [\gamma, t')$, $R(t) = \{\mathcal{B}\}$.

(k) Either $\mathcal{K}$ or $\mathcal{Q}$ calls $\texttt{doCollect}()$, specifically during $[I_2^-, \gamma]$.

**Proof.** Proof of (a): We first show that for all $t \in [I_2^-, \min(\lambda_\mathcal{K}, \lambda_\mathcal{Q})]$, $R(t) = \{\mathcal{K}, \mathcal{Q}\}$ and then show that $\lambda = \min(\lambda_\mathcal{K}, \lambda_\mathcal{Q})$. From Claims \textbf{D.24}\texttt{(a)} \texttt{K} calls $\texttt{helpRelease}_\mathcal{K}()$ in line $50$ after time $I_2^-$. From Claim \textbf{D.24}\texttt{(a)}, \texttt{K} is a releaser of $L$ at time $I_2^-$. From an inspection of Figures $S$ and $Q$ throughout $[I_2^-, \min(\lambda_\mathcal{K}, \lambda_\mathcal{Q})]$ \texttt{K} does not execute a call to $\texttt{helpRelease}_\mathcal{K}()$ or $\texttt{doPromote}_\mathcal{K}()$. Also from an inspection, \texttt{K} fails to decrease $\texttt{Ctr}$ from $1$ to $0$ at $t_\mathcal{K}$, thus \texttt{K}'s cease-release event $\phi_\mathcal{K}$ does not occur. Since \texttt{K}'s cease-release events $\pi_\mathcal{K}, \pi_\mathcal{Q}$ and $\theta_\mathcal{K}$ only occur during $\texttt{helpRelease}_\mathcal{K}()$ or $\texttt{doPromote}_\mathcal{K}()$ (Claims \textbf{D.7}\texttt{(c)} and \textbf{D.7}\texttt{(f)}), it follows that $\mathcal{K}$ is a releaser of $L$ throughout $[I_1^-, \min(\lambda_\mathcal{K}, \lambda_\mathcal{Q})]$. From Claim \textbf{D.24}\texttt{(b)}, \texttt{Q} calls $\texttt{helpRelease}_\mathcal{Q}()$, respectively either in line $30$ or line $43$ after time $I_2^-$. From Claim \textbf{D.24}\texttt{(a)}, \texttt{Q} is a releaser of $L$ at time $I_2^-$. From an inspection of Figures $I$ and $I$ throughout $[I_2^-, \min(\lambda_\mathcal{K}, \lambda_\mathcal{Q})]$ \texttt{Q} does not execute a call to $\texttt{helpRelease}_\mathcal{Q}()$ or $\texttt{doPromote}_\mathcal{Q}()$. Also from an inspection, \texttt{Q} does not execute a $\texttt{Ctr.CAS}(1, 0)$ operation in line $38$ and thus \texttt{Q}'s cease-release event $\phi_\mathcal{Q}$ does not occur. Since \texttt{Q}'s cease-release events $\pi_\mathcal{K}, \pi_\mathcal{Q}$ and $\theta_\mathcal{Q}$ only occur during $\texttt{helpRelease}_\mathcal{Q}()$ or $\texttt{doPromote}_\mathcal{Q}()$ (Claims \textbf{D.7}\texttt{(c)} and \textbf{D.7}\texttt{(f)}), it follows that \texttt{Q} is a releaser of $L$ throughout $[I_2^-, \min(\lambda_\mathcal{K}, \lambda_\mathcal{Q})]$. Then for all $t \in [I_2^-, \min(\lambda_\mathcal{K}, \lambda_\mathcal{Q})]$, $\{\mathcal{K}, \mathcal{Q}\} \subseteq R(t)$ since $I_1^- < I_2^-$ and $\min(\lambda_\mathcal{K}, \lambda_\mathcal{Q}) = \min(\lambda_\mathcal{K}, \lambda_\mathcal{Q})$. From Claim \textbf{D.24}\texttt{(f)}, it follows that a process can become a releaser during $I_2$ only if it is promoted by a releaser of $L$. Then to show that for all $t \in [I_2^-, \min(\lambda_\mathcal{K}, \lambda_\mathcal{Q})]$, $R(t) = \{\mathcal{K}, \mathcal{Q}\}$, we need to show that no process is promoted by $\mathcal{K}$ or $\mathcal{Q}$ during $[I_2^-, \min(\lambda_\mathcal{K}, \lambda_\mathcal{Q})]$. If a process was promoted by $\mathcal{K}$ or $\mathcal{Q}$ during $[I_2^-, \min(\lambda_\mathcal{K}, \lambda_\mathcal{Q})]$ then by definition cease-release events $\pi_\mathcal{K}$ or $\pi_\mathcal{Q}$ would have occurred during $[I_2^-, \min(\lambda_\mathcal{K}, \lambda_\mathcal{Q})]$, but as shown above this does not happen.

From Claim \textbf{D.24}\texttt{(a)}, $\texttt{Sync2} = \bot$ at time $I_2^-$. From a code inspection, $\texttt{Sync2}$ is changed to a non-$\bot$ value only in line $56$ (during $\texttt{helpRelease}()$), moreover only by a releaser of $L$ (from Claim \textbf{D.15}). Since for all $t \in [I_2^-, \min(\lambda_\mathcal{K}, \lambda_\mathcal{Q})]$, $R(t) = \{\mathcal{K}, \mathcal{Q}\}$ and $\min(\lambda_\mathcal{K}, \lambda_\mathcal{Q}) = \min(\lambda_\mathcal{K}, \lambda_\mathcal{Q})$, it follows then that $\texttt{Sync2} = \bot$ throughout $[I_2^-, \min(\lambda_\mathcal{K}, \lambda_\mathcal{Q})]$ and $\mathcal{A}$ executes a successful $\texttt{Sync2.CAS}(\bot, \bot, \lambda)$ operation in line $56$. Thus $\mathcal{A}$'s cease-release event $\tau_\mathcal{A}$ occurs at $t_\mathcal{A}$.

Since $\texttt{Sync2} = \bot$ throughout $[I_0^-, I_1^-]$ (Claims \textbf{D.23}\texttt{(a)} and \textbf{D.23}\texttt{(g)}) and throughout $[I_2^-, \min(\lambda_\mathcal{K}, \lambda_\mathcal{Q})]$, it follows that $\texttt{Sync2}$ was changed to a non-$\bot$ value for the first time at $t_\mathcal{A}$, thus $\lambda = t_\mathcal{A}$. Then it follows for all $t \in [I_2^-, \lambda)$, $R(t) = \{\mathcal{K}, \mathcal{Q}\}$, and $\texttt{Sync2} = \bot$ throughout $[I_2^-, \lambda)$.

**Proof of (b):** From Part (a), $\mathcal{A}$'s cease-release event $\tau_\mathcal{A}$ occurs at $\lambda = t_\mathcal{A}$, and thus $\mathcal{A}$'s $\texttt{Sync2.CAS}(\bot, \bot, \lambda)$ operation in line $56$ succeeds. Then from the code structure $\mathcal{A}$ does not satisfy the if-condition on line $56$ and returns from its call to $\texttt{helpRelease}_\mathcal{A}()$. Thus, Figure $12$ follows.

**Proof of (c), (d), (e), (f), (g), (h), (i) and (j):** From Part (a), $\lambda = t_\mathcal{A}$ and for all $t \in [I_2^-, \lambda)$, $R(t) = \{\mathcal{K}, \mathcal{Q}\}$ and $\texttt{Sync2} = \bot$ throughout $[I_2^-, \lambda)$ and cease-release event $\tau_\mathcal{A}$ occurs at $\lambda$. Then $\mathcal{A}$ ceases to be a releaser of $L$ at $\lambda$, and thus $R(\lambda) = \{\mathcal{B}\}$ and $\texttt{Sync2} = \mathcal{A} \neq \bot$ at $\lambda$. From
Claim \( \text{D.24(c)} \) it follows that \( B \) will continue to be the only releaser of \( L \) until the point when \( B \) ceases to be a releaser of \( L \) or promotes another process. Let \( t > \lambda \) be the point in time when \( B \) ceases to be a releaser of \( L \). Since \( B \) ceases to be a releaser of \( L \) if it promotes another process (by definition of cease-release event \( \pi_B \)), it follows that \( B \) is the only releaser of \( L \) throughout \( [\lambda, t) \).

Then from Claim \( \text{D.15} \) it follows that \( B \) has exclusive write-access to \( \text{PawnSet} \) and exclusive registration-access to \( \text{PawnSet} \) throughout \( [\lambda, t) \).

Now consider \( B \)'s \( \text{helpRelease}_B() \) call. Since \( \lambda = t_{65}^A < t_{65}^B \) and \( \text{Sync2} \neq \perp \) at \( \lambda \) and \( B \) has exclusive write-access to \( \text{Sync2} \) throughout \( [\lambda, t) \), \( B \) fails the \( \text{Sync2.CAS(\perp, B)} \) operation at \( t_{65}^B \), and thus satisfies the if-condition of line \( 66 \). It then executes lines \( 67-68 \) and calls \( \text{doPromote}_B() \) in line \( 69 \). Then Figures \( 13 \) and \( 14 \) and Part (d) follows immediately.

We now show that \( \gamma = t_{65}^B \leq t \). Since \( \lambda = t_{65}^A < t_{65}^B < t_{65}^\perp \), it would follow that \( \lambda < \gamma \), and hence we would have proved Part (d). And since \( B \) is the only releaser of \( L \) throughout \( [\lambda, t) \), we would have proved Part (e) as well, i.e., \( B \) is the only releaser throughout \( [\lambda, t) \).

During \( \text{doPromote}_B() \), \( B \) executes a \( \text{PawnSet.promote()} \) operation in line \( 65 \). Since \( K \) and \( Q \) are the first two releasers of \( L \) during \( T \) (Claim \( \text{D.24(b)} \)), and only a releaser executes a \( \text{PawnSet.promote()} \) operation (Claim \( \text{D.18} \)), and \( A \) ceased to be a releaser at \( t_{64}^A < t_{65}^B \), it follows that \( B \)'s \( \text{PawnSet.promote()} \) operation in line \( 65 \) is the first \( \text{PawnSet.promote()} \) operation, and thus \( \gamma = t_{65}^B \). Since none of \( B \)'s cease-release events occur during \( [t_{65}^B, t_{66}^\perp) \), \( t \geq t_{65}^B \).

During \( [t_{65}^B, t_{66}^\perp) \), \( B \) resets \( \text{Sync1} \) and \( \text{Sync2} \) in lines \( 68 \) and \( 69 \) respectively, and since \( B \) has exclusive write-access to \( \text{Sync1} \) and \( \text{Sync2} \) throughout \( [t_{65}^B, t_{66}^\perp) \), at time \( \gamma = t_{65}^B \), \( \text{Sync1} = \text{Sync2} = \perp \). Thus, Part (f) follows.

By definition \( \gamma \) is the point in time when the first \( \text{PawnSet.promote()} \) operation occurs. Since a promotion event occurs only when a \( \text{PawnSet.promote()} \) operation returns a non-\( (\perp, \perp) \) value, it follows that no promotion event occurs during \( [I_0^B, \gamma) \). Hence, Part (g) follows.

Since \( B \) has exclusive write-access to \( \text{Sync2} \) throughout \( [\lambda, t_{65}^B] \), and \( \text{Sync2} = A \) at \( \lambda > t_{65}^B \), \( B \) reads the value \( A \) from \( \text{Sync2} \) in line \( 65 \), and executes a \( \text{ PawnSet.remove(A)} \) operation in line \( 61 \). Since \( B \) executes \( \text{ PawnSet.remove(A)} \) and \( \text{ PawnSet.remove(B)} \) in lines \( 61 \) and \( 64 \) during \( [\lambda, \gamma) \) and \( B \) has exclusive registration-access to \( \text{ PawnSet } \) during \( [\lambda, \gamma) \), it follows from the semantics of the \( \text{AbortableProArray}_{\eta} \) object that \( B \)'s \( \text{ PawnSet.promote()} \) operation at time \( \gamma \) does not return values in \( \{a, b \mid a \in \{A, B\}, b \in \mathbb{N}\} \). Hence, Part (h) follows.

**Case a -** \( B \)'s \( \text{ PawnSet.promote()} \) operation returns a non-\( (\perp, \perp) \) value: Then \( B \)'s cease-release event \( \pi_B \) occurs at \( t_{65}^B = \gamma \) (Claim \( \text{D.18} \)), and thus Part (i) holds.

**Case b -** \( B \)'s \( \text{ PawnSet.promote()} \) operation in line \( 65 \) returns \( (\perp, \perp) \). Then \( B \) did not find any process to promote, and thus cease-release event \( \pi_B \) did not occur. From the code structure \( B \) goes on to execute a \( \text{Ctr.CAS(2,0)} \) operation in line \( 68 \). Since \( \text{Ctr} = 2 \) throughout \( I_2 \), it follows that \( B \)'s \( \text{Ctr.CAS(2,0)} \) operation succeeds, and thus \( B \)'s cease-release event \( \theta_B \) occurs at \( t_{68}^B \) and the intervals \( I_2 \) and \( T \) end. Therefore \( t' = t_{68}^B > t_{68}^\perp = \gamma \). Clearly, \( B \) does not promote any process in \( [t_{68}^B, t_{68}^\perp) \) and \( [\gamma, t') \), and thus Part (i) holds.

**Proof of (k):** From an inspection of Figure \( 9 \) \( K \) executes a \( \text{Sync1.CAS(\perp, K)} \) operation in line \( 37 \). Since \( I_2^K < t_{37}^K < t_{37}^\perp < t_{68}^B < \gamma \) (from Parts (g) and (i)), it follows that \( t_{37}^K \in [I_2^K, \gamma) \). From an inspection of Figures \( 10 \) and \( 11 \) \( Q \) may or may not execute a \( \text{Sync1.CAS(\perp, \perp)} \) operation in line \( 26 \) if \( Q \) executes a \( \text{Sync1.CAS(\perp, \perp)} \) operation in line \( 26 \) since \( I_2^Q < t_{26}^Q < t_{68}^\perp < \gamma \), it follows that \( t_{26}^Q \in [I_2^Q, \gamma) \).

Since for all \( t \in [I_2^K, \gamma) \), \( R(t) \subseteq \{K, Q\} \) (from Parts (g) and (i)), and only releasers of \( L \) have write-access to \( \text{Sync1} \) (Claim \( \text{D.15} \)), and \( \text{Sync1} = \perp \) at \( I_2^K \) (Claim \( \text{D.24(m)} \)), it follows that either \( K \) or \( Q \) executes a successful \( \text{CAS()} \) operation on \( \text{Sync1} \). Then from the code structure it
follows that either $\mathcal{K}$ or $\mathcal{Q}$ executed a call to $\text{doCollect()}$ in lines 88 or 29, respectively. Since $\frac{\ell_3}{\ell_4} < \frac{\ell_4}{\ell_5} = \frac{\ell_3}{\ell_5} < \gamma$ and $\frac{\ell_2}{\ell_3} < \frac{\ell_3}{\ell_4} < \gamma$, $\mathcal{K}$ or $\mathcal{Q}$ executed a call to $\text{doCollect()}$ during $[I_2, \gamma]$. 

Claim D.26. If a process $p$ is promoted at time $t' \in T$ and a $\text{PawnSet.reset()}$ has not been executed during $[I_0^-, t']$, then $p$ did not execute a $\text{PawnSet.abort}(p, s)$ operation during $[I_0^-, t']$, where $s \in \mathbb{N}$.

Proof. Suppose not, i.e., $p$ executed a $\text{PawnSet.abort}(p, s)$ operation at time $t < t'$. Since $p$ has not been promoted before $t' > t$ it follows that a $\text{PawnSet.promote()}$ operation that returns $\langle p, \cdot \rangle$ has not been executed before $t$. Then from Claim D.5 and the semantics of $\text{PawnSet}$, it follows that the $p$-th entry of $\text{PawnSet}$ is not at value $\langle \text{PRO}, s \rangle = (2, s)$ throughout $[I_0^-, t]$. Then $p$'s $\text{PawnSet.abort}(p, s)$ operation at $t$ succeeds, and thus $p$ writes value $\langle \text{ABORT}, s \rangle = (3, s)$ to the $p$-entry of $\text{PawnSet}$. Then for $p$ to be promoted at $t' > t$, it follows from the semantics of $\text{PawnSet}$ and Claim D.5, that during $[t, t')$ a $\text{PawnSet.reset()}$ operation and then a $\text{PawnSet.collect}(A)$ operation where $A[p] = s$, must be executed, followed by a $\text{PawnSet.promote()}$ at $t'$ that returns $\langle p, s \rangle$. This is a contradiction to the assumption that a $\text{ PawnSet.reset()}$ is not executed during $[I_0^-, t']$. 

Let $\ell$ be the number of times a promotion occurs during $T$. For all $i \in \{1, \ldots, \ell\}$, define $\Omega_i$ to be the $i$-th interval $[\Omega_i^-, \Omega_i^+]$ that begins when the $i$-th promotion occurs during $T$ and ends when the promoted process ceases to be a releaser of $L$. Let $\mathcal{P}_i$ be the process promoted at $\Omega_i^-$. 

Claim D.27. If $\Omega_2 \neq \emptyset$ and $R(I_0^-) = \emptyset$ and at time $I_0^-$, $\text{Sync1} = \text{Sync2} = \perp$ and $\text{PawnSet}$ is candidate-empty, then the following claims hold for all $i \in \{1, \ldots, \ell\}$:

(a) If $\ell \geq 1$, then $\gamma = \Omega_1^-$ and $R(\Omega_1^-) = \{\mathcal{P}_1\}$, and $\text{Sync1} = \text{Sync2} = \perp$ at $\Omega_1^-$, and no $\text{PawnSet.reset()}$ operation has been executed during $[I_0^-, \Omega_1^-]$.

(b) If $R(\Omega_i^-) = \{\mathcal{P}_i\}$, then for all $t \in [\Omega_i^-, \Omega_i^+]$, $R(t) = \{\mathcal{P}_i\}$. (i.e., $\mathcal{P}_i$ is the only releaser throughout $\Omega_i$)

(c) If $i \neq \ell$ and $R(\Omega_i^-) = \{\mathcal{P}_i\}$, then $\Omega_i^+ = \Omega_{i+1}^-$ and $R(\Omega_{i+1}^-) = \{\mathcal{P}_{i+1}\}$. (i.e., $\mathcal{P}_{i+1}$ is the only releaser at $\Omega_{i+1}^-$)

(d) If $i \neq \ell$, then $\Omega_i^+ = \Omega_{i+1}^-$ and $R(\Omega_{i+1}^-) = \{\mathcal{P}_{i+1}\}$.

(e) For all $t \in [\Omega_i^-, \Omega_i^+]$, $R(t) = \{\mathcal{P}_i\}$. (i.e., $\mathcal{P}_i$ is the only releaser throughout $\Omega_i$).

Proof. Proof of (a): If the $\text{PawnSet.promote()}$ operation at time $\gamma$ returns value $(\perp, \perp)$, then from Claims D.25 and D.25 it follows that no promotion occurs during $T$, which is a contradiction to $\ell \geq 1$. Thus, the $\text{PawnSet.promote()}$ operation at time $\gamma$ returns a non-$\langle \perp, \perp \rangle$ value. By definition $\gamma$ is the point when the first $\text{ PawnSet.promote()}$ operation occurs, and $\Omega_1^-$ is the point when the first promotion occurs and $\mathcal{P}_1$ is the process promoted at $\Omega_1^-$. Then $\gamma = \Omega_1^-$, and $\mathcal{P}_1$ is the first promoted process. From Claim D.25, $B$ is the only releaser of $L$ at the point in time immediately before time $\gamma$. Then from Claim D.25 it follows that $B$ promotes $\mathcal{P}_1$ at time $\gamma = \Omega_1^-$, and $B$ ceases to be a releaser of $L$ at $\gamma$, therefore $R(\gamma) = \{\mathcal{P}_1\}$. From Claim D.25 it follows that $\text{Sync1} = \text{Sync2} = \perp$ at $\Omega_1^-$. 

From an inspection of the code, a $\text{PawnSet.reset()}$ is executed only in line 67 and it can be executed only after a $\text{PawnSet.promote()}$ is executed in line 65. Since $\gamma$ is the first point when a $\text{PawnSet.promote()}$ is executed, it follows that no $\text{PawnSet.reset()}$ operation was executed during $[I_0^-, \gamma]$. 

47
Proof of (b): Since \( R(\Omega^{-}_i) = \{P_i\} \), and \( \Omega^+_i \) is the point when \( P_i \) ceases to be a releaser of \( L \), for all \( t \in [\Omega^{-}_i, \Omega^+_i) \), \( \{P_i\} \subseteq R(t) \). To show that for all \( t \in [\Omega^{-}_i, \Omega^+_i) \), \( R(t) = \{P_i\} \), we need to show that no other process becomes a releaser of \( L \), during \( [\Omega^{-}_i, \Omega^+_i) \). Suppose some process \( q \neq P_i \) becomes a releaser of \( L \) some time during that interval. Since \( \Omega^{-}_i > \Omega^+_i = \gamma > I_2^- \), from Claim D.24(d) it follows that \( P_i \) promotes \( q \) during \( [\Omega^{-}_i, \Omega^+_i) \). Then from Claim D.18 \( P_i \)'s cease-release event \( \pi_{P_i} \) occurs during \( [\Omega^{-}_i, \Omega^+_i) \), and thus \( P_i \) ceases to be a releaser of \( L \) during \( [\Omega^{-}_i, \Omega^+_i) \). Hence a contradiction.

Proof of (c): Since \( i < \ell \), it follows that there exists a process \( P_{i+1} \) that becomes a releaser of \( L \) during \( T \). By definition, \( P_i \) and \( P_{i+1} \) are the \( i \)-th and \( (i+1) \)-th promoted processes during \( T \), respectively. Since \( \Omega^{-}_{i+1} > \Omega^{-}_i > \Omega^{-}_1 = \gamma > I_2^- \), from Claim D.24(e) it follows that no other process becomes a releaser after \( P_i \) became a releaser and before \( P_{i+1} \) becomes a releaser, i.e., during \( [\Omega^{-}_{i+1}, \Omega^+_{i+1}) \). Moreover, since \( R(\Omega^{-}_i) = \{P_i\} \), it follows that the next process to be promoted, i.e., \( P_{i+1} \), is promoted by the only releaser of \( L \), \( P_i \). Then from Claim D.18 it follows that \( P_i \) promotes \( P_{i+1} \) by executing a \( \textsc{PawnSet} \cdot \text{promote}() \) in line 65 that returns \( \langle P_{i+1}, s \rangle \), where \( s \in \mathbb{N} \), and event \( \pi_{P_i} \) occurs at \( t_{P_i}^65 \). Then \( P_i \) ceases to be a releaser of \( L \) at \( t_{P_i}^65 \) and thus \( \Omega^+_{i+1} = t_{P_i}^65 \). Since \( \Omega^+_{i+1} \) is the point when \( P_{i+1} \) becomes a releaser of \( L \), it follows that \( \Omega^+_i = \Omega^+_{i+1} \), and thus \( R(\Omega^+_{i+1}) = \{P_{i+1}\} \).

Proof of (d): We prove by induction that for all \( k < \ell \), \( R(\Omega^{-}_{k+1}) = \{P_{k+1}\} \) and \( \Omega^+_{k} = \Omega^+_{k+1} \).

Basis \((k = 1) \) From Part (a), \( P_1 \) is the only releaser of \( L \) at \( \Omega^+_1 \), and clearly \( \ell > k = 1 \). Then from Part (c), \( \Omega^+_i = \Omega^+_1 \) and \( R(\Omega^+_1) = \{P_1\} \).

Induction step \((k > 1) \) By definition \( P_k \) is the promoted process at \( \Omega^+_k \), and since \( |R(\Omega^+_{k-1})| = 1 \) and \( \Omega^+_{k-1} = \Omega^+_k \) (by the induction hypothesis), it follows that \( P_k \) is the only releaser of \( L \) at \( \Omega^+_k \). Then from Part (c), \( \Omega^+_k = \Omega^+_{k+1} \) and \( R(\Omega^+_{k+1}) = \{P_{k+1}\} \).

Proof of (e): From Part (a), \( R(\Omega^+_1) = \{P_1\} \), and thus from Part (b), for all \( t \in [\Omega^{-}_1, \Omega^+_1) \), \( R(t) = \{P_1\} \). From Part (d), for all \( i > 1 \), \( R(\Omega^-_i) = \{P_i\} \), and thus from Part (b), for all \( t \in [\Omega^{-}_i, \Omega^+_i) \), \( R(t) = \{P_i\} \). Hence, our claim follows.

Claim D.28. If \( I_2 \neq \emptyset \) and \( R(I^-_0) = \emptyset \) and at time \( I^-_0 \), \( \text{Sync1} = \text{Sync2} = \bot \) and \( \text{PawnSet} \) is candidate-empty, then the following claims hold for all \( i \in \{1, \ldots, \ell\} \):

(a) A \( \textsc{PawnSet} \cdot \text{reset}() \) operation is not executed during \( [I^-_0, \Omega^-_i) \).

(b) \( P_i \) executes lines of code of \( \text{lockP}_i() \) starting with line 34 as depicted in Figure 15.

(c) \( P_i \)'s call to \( \text{lockP}_i() \) returns \( \infty \), and \( P_i \) finishes \( \text{lockP}_i() \) during \( T \), and \( \text{Role}[P_i] = \textsc{Pawn}_P \) when \( P_i \)'s call to \( \text{lockP}_i() \) returns.

(d) Exactly one cease-release event among \( \pi_{P_i} \) and \( \theta_{P_i} \) occurs during \( P_i \)'s call to \( \text{doPromoteP}_i() \).

(e) \( P_i \) executes lines of code of \( \text{releaseP}_i() \) starting with line 34 as depicted in Figure 16.

(f) \( P_i \) does not write to \( \text{Sync1} \) or \( \text{Sync2} \) during \( [\Omega^-_i, \Omega^+_i) \).

(g) \( t_{P_i}^{34} < \Omega^-_i < t_{P_i}^{49} < \Omega^+_i < t_{P_i}^{49} \) and \( \Omega^+_i \leq I^+_2 \).

(h) If \( i \neq \ell \), then a \( \textsc{PawnSet} \cdot \text{reset}() \) operation is not executed during \( [I^-_0, \Omega^+_i) \).

(i) Throughout \( [\gamma, \Omega^+_i) \), \( \text{Sync1} = \text{Sync2} = \bot \).

(j) If \( \ell > 1 \), \( I^+_2 = \Omega^+_\ell = t_{P_\ell}^{65} \).

(k) For all \( t \in [\gamma, I^+_2) \), \( R(t) = 1 \).
(i) \( R(I^+_2) = \emptyset \) and at \( I^+_2 \), \( \text{Sync}1 = \text{Sync}2 = \perp \) and \( \text{PawnSet} \) is candidate-empty.

**Proof.** Proof of (a)-(h): We prove Parts (a)-(h) by induction on \( i \). First, we prove Part (a) for \( i = 1 \). Second, we show that if Part (a) is true for a fixed \( i \), then Parts (b)-(h) are true for \( i \). Finally, we show that if Parts (a)-(h) are true for \( i \), then Part (a) is true for \( i+1 \), thus completing the proof.

From Claim D.27(a), no \( \text{PawnSet}.\text{reset}() \) operation has been executed during \( [I^-_1, \Omega^-_1] \). Hence, Part (a) for \( i = 1 \) holds.

Now we show that if Part (a) is true for a fixed \( i \), then Parts (b)-(h) follow for \( i \).

**Proof of Parts (b) and (c) if Part (a) for \( i \) is true:** Let \( q \) be the process that promotes \( P_i \) at \( \Omega^-_i \). Then \( q \)'s \( \text{PawnSet}.\text{promote}() \) operation in line 65 returned value \( \langle P_i, s \rangle \) where \( s \in \mathbb{N} \), and \( \Omega^-_i = t^-_{65} q \). Then from the semantics of the \( \text{PawnSet} \) object it follows that the \( P_i \)-th entry of \( \text{PawnSet} \) was \( \langle \text{REG}, s \rangle = \langle 1, s \rangle \) immediately before \( \Omega^-_i \). Then from Claim D.5(b) it follows that some process (say \( r \)) executed a \( \text{PawnSet}.\text{collect}(A) \) operation in line 55 where \( A[P_i] = s \). Then from the code structure, \( r \) read \( \text{apply}[P_i] = \langle \text{REG}, s \rangle \) in line 52. By Claim D.6(a) \( \text{apply}[P_i] \) is set to value \( \langle \text{REG}, s \rangle \) only by process \( P_i \) when it executes a successful \( \text{apply}[P_i].\text{CAS}(\langle \perp, \perp \rangle, \langle \text{REG}, s \rangle) \), therefore \( P_i \) executed the same and broke out of the spin loop of line 2. Note that \( t^-_{65} q < t^-_{52} < \Omega^-_i = t^-_{65} \).

Since \( \text{Ctr} = 0 \) throughout \( I_0 \), \( \text{Ctr} = 1 \) throughout \( I_1 \) and \( \text{Ctr} = 2 \) throughout \( I_2 \), it follows that \( \text{Ctr} \) is increased only at points \( I^-_1 \) and \( I^-_2 \) during \( T \). Since \( K \) and \( Q \) are the first two releasers of \( L \) and they increased \( \text{Ctr} \) to 1 and 2, respectively, at \( I^-_1 \) and \( I^-_2 \), respectively, it follows that no other process apart from \( K \) and \( Q \) increases the value of \( \text{Ctr} \) during \( T \). Since \( \Omega^-_1 \geq \Omega^-_1 = \gamma > I^-_2 \) (by Claims D.25(a) and D.25(b) and D.27(a)), \( P_i \) becomes a releaser of \( L \) only after \( I^-_2 \) (the point at which \( Q \) became a releaser of \( L \)). Thus, \( P_i \) is not among the first two releasers of \( L \), thus \( P_i \notin \{K, Q\} \). Then it follows that \( P_i \) does not increase \( \text{Ctr} \). Therefore \( P_i \)'s \( \text{Ctr}.\text{inc}() \) operation in
line 5 returns value 2 = PAWN, and thus \( \mathcal{P}_i \) sets Role[\( \mathcal{P}_i \)] to 2 = PAWN in line 6. Then from the code structure \( \mathcal{P}_i \) satisfies the if-condition of line 6 and proceeds to spin in line 7.

**Case a - \( \mathcal{P}_i \) receives a signal to abort while busy-waiting in line 7.** Then \( \mathcal{P}_i \) stops spinning in line 7 and executes \( \text{abort}_{\mathcal{P}_i}(\cdot) \). Since \( \mathcal{P}_i \) last set Role[\( \mathcal{P}_i \)] to PAWN in line 5 it then follows from the code structure that \( \mathcal{P}_i \) proceeds to execute lines 18-20 and satisfies the if-condition of line 20 and then executes a \( \text{PawnSet.abort}(\mathcal{P}_i, s) \) operation in line 21.

Since a \( \text{PawnSet.reset}() \) operation has not been executed during \([I_0, \Omega^-_i]\), from Claim \( [\Omega^-_i, \Omega^+_i] \) it follows that \( \mathcal{P}_i \) did not execute a \( \text{PawnSet.abort}(\mathcal{P}_i, s) \) operation in line 21 during \([I_0, \Omega^-_i]\), thus \( t_{\mathcal{P}_i} \) > \( \Omega^-_i \). Since \( \mathcal{P}_i \) has exclusive-registration access to PawnSet during \([\Omega^-_i, \Omega^+_i]\), and \( \mathcal{P}_i \) has not executed any of its cease-release events or reset PawnSet during \([t_{\mathcal{P}_i}, \Omega^+_i]\), and \( t_{\mathcal{P}_i} < \Omega^-_i \), it then follows that PawnSet was not reset during \([\Omega^-_i, \Omega^+_i]\). Then since the \( \mathcal{P}_i \)-th entry of PawnSet was last changed to \( \langle \text{PRO}, s \rangle = \langle 2, s \rangle \) at \( \Omega^-_i \), it remains \( \langle \text{PRO}, s \rangle \) throughout \([\Omega^-_i, \Omega^+_i]\). Then \( \mathcal{P}_i \)'s \( \text{PawnSet.abort}(\mathcal{P}_i, s) \) operation in line 21 returns \text{false} by the semantics of the PawnSet object. Then \( p \) satisfies the if-condition of line 21 proceeds to set Role[\( \mathcal{P}_i \)] to PAWN P in line 22 and then returns \( \infty \) from its call to \( \text{abort}_{\mathcal{P}_i}(\cdot) \) and \( \text{lock}_{\mathcal{P}_i}(\cdot) \).

**Case b - \( \mathcal{P}_i \) does not receive a signal to abort while busy-waiting in line 7.**

Recall that process \( q \) promotes \( \mathcal{P}_i \) at \( \Omega^-_i \) by executing a \( \text{PawnSet.promote}() \) operation in line 65 that returns value \( \langle \mathcal{P}_1, s \rangle \), where \( s \in \mathbb{N} \). Since processes in the system continue to take steps, process \( q \) sets its local variable \( j \) to value \( \mathcal{P}_i \) in line 65 and proceeds to fail the if-condition of line 66 and then executes line 70 where \( \langle j, \text{seq} \rangle = \langle \mathcal{P}_i, s \rangle \). Then \( q \) executes a \( \text{apply[\mathcal{P}_i].CAS(\langle REG, s \rangle, \langle \text{PRO}, s \rangle) \) operation in line 70.

Recall that process \( r \) read value \( \text{apply[\mathcal{P}_i]} = \langle \text{REG, s} \rangle \) in line 52 and \( t_{\mathcal{P}_i} \) < \( t_{\mathcal{P}_j} \) < \( \Omega^-_i = \Omega^-_{\mathcal{P}_i} \). From an inspection of the code, \( \text{apply[\mathcal{P}_i]} \) can change from value \( \langle \text{REG, s} \rangle \) only to value \( \langle \text{PRO, s} \rangle \) and from value \( \langle \text{PRO, s} \rangle \) only to value \( \langle \bot, \bot \rangle \). Also, \( \text{apply[\mathcal{P}_i]} \) can be changed from \( \langle \text{PRO, s} \rangle \) to \( \langle \bot, \bot \rangle \), only if \( p \) executes line 32 or 49. Since \( p \) is spinning in line 7 it follows that a \( \text{apply[\mathcal{P}_i].CAS(\langle \text{PRO, s}, \langle \bot, \bot \rangle \) operation is not executed during \([\Omega^-_i, t_{\mathcal{P}_j}]\), and thus \( \text{apply[\mathcal{P}_i]} = \langle \text{REG, s} \rangle \) throughout \([\Omega^-_i, t_{\mathcal{P}_j}]\). Therefore, \( q \) executes a successful \( \text{apply[\mathcal{P}_i].CAS(\langle \text{REG, s}, \langle \text{PRO, s} \rangle \) operation in line 70 and thus \( \text{apply[\mathcal{P}_i]} = \langle \text{PRO, s} \rangle \) at \( t_{\mathcal{P}_j} \).

Since \( \mathcal{P}_i \) is busy-waiting in line 7 for \( \text{apply[\mathcal{P}_i]} \) to change to \( \langle \text{PRO, s} \rangle \), it then follows that \( \mathcal{P}_i \) busy-waits throughout \([\Omega^-_i, t_{\mathcal{P}_j}]\), and reads \( \text{apply[\mathcal{P}_i]} = \langle \text{PRO, s} \rangle \) when it executes line 7 for the first time after \( t_{\mathcal{P}_j} \). Then \( \mathcal{P}_i \) breaks out of the spin loop, and then from the code structure, \( \mathcal{P}_i \) proceeds to set Role[\( \mathcal{P}_i \)] to PAWN P in line 9 breaks out of the role-loop in line 12 executes line 13 and fails the if-condition of line 14 and executes lines 16-17 and returns from \( \text{lock}_{\mathcal{P}_i}(\cdot) \) in line 17 with value \( \infty \). Note that \( \Omega^-_i < t_{\mathcal{P}_j} \).

**Proof of Parts (1), (2), and (3) if Part (4) for \( i \) is true:** Since \( \mathcal{P}_i \) is the only releaser of \( L \) throughout \([\Omega^-_i, \Omega^+_i] \) (Claim \( [\Omega^-_i, \Omega^+_i] \)), it follows from Claim \( [\Omega^-_i, \Omega^+_i] \) that \( \mathcal{P}_i \) has exclusive-write-access to objects Sync1 and Sync2 and exclusive-registration-access to PawnSet throughout \([\Omega^-_i, \Omega^+_i] \).

Since \( \mathcal{P}_i \) returns from its call to \( \text{lock}_{\mathcal{P}_i}(\cdot) \) with value \( \infty \) (by Part (3)), \( \mathcal{P}_i \) executes a call to \( \text{release}_{\mathcal{P}_i}(\cdot) \) (follows from conditions 6 and 14).

Since \( \text{Role[\mathcal{P}_i]} = \text{PAWN}_P \) when \( \mathcal{P}_i \)'s call to \( \text{lock}_{\mathcal{P}_i}(\cdot) \) returns (by Part (2)), \( \text{Role[\mathcal{P}_i]} = \text{PAWN}_P \) at \( t_{\mathcal{P}_i} \). Since \( \text{Role[\mathcal{P}_i]} \) is unchanged during \([t_{\mathcal{P}_i}, t_{\mathcal{P}_j}] \) (follows from Claim \( [\Omega^-_i, \Omega^+_i] \)), it follows from the code structure that during \( \mathcal{P}_i \)'s call to \( \text{release}_{\mathcal{P}_i}(j) \), \( \mathcal{P}_i \) only executes lines 33, 35, 32 and 15-50. Then Figure 10 follows.

From an inspection of Figures 15 and 16, \( \mathcal{P}_i \) does not execute a call to \( \text{helpRelease}_{\mathcal{P}_i}(\cdot) \) or execute a \( \text{Ctr.CAS(1, 0)} \) operation in line 66 during \( \text{release}_{\mathcal{P}_i}(\cdot) \). Then from Claims \( [\Omega^-_i, \Omega^+_i] \) and \( [\Omega^-_i, \Omega^+_i] \), \( \mathcal{P}_i \)'s cease-release events \( \phi_{\mathcal{P}_i} \) and \( \tau_{\mathcal{P}_i} \) do not occur. Since \( \mathcal{P}_i \) executes a call to \( \text{doPromote}_{\mathcal{P}_i}(\cdot) \) only
in line 46, it follows from Claim D.19 that exactly one cease-release event among \( \pi_i \)'s call to \( \text{doPromote}_i() \). Hence, Part (i) follows. Then \( \Omega_i^+ \) is the point when cease-release event \( \pi_i \) or \( \theta_i \) occurs. From an inspection of Figures 15 and 16 and the code, it is clear that \( \pi_i \) does not change Sync1 or Sync2 during lock\( _{\pi_i}() \) and release\( _{\pi_i}() \). Therefore, \( \pi_i \) does not change Sync1 or Sync2 during \([\Omega_i^-, \Omega_i^+\]).

**Proof of Part (m) if Part (a) for \( i \) is true:** As argued in Part (i), exactly one cease-release event among \( \pi_i \) and \( \theta_i \) occurs during \( \pi_i \)'s call to \( \text{doPromote}_i() \). If cease-release event \( \theta_i \) occurs then \( \Omega_i^+ \) is the point when \( \pi_i \)'s cease-release event \( \theta_i \) occurs, i.e., \( \Omega_i^+ = \ell_{\pi_i} \). Then \( \pi_i \) changes Ctr to 0 and the Ctr-cycle interval \( T \) ends at \( \Omega_i^+ = \ell_{\pi_i} = I_2^+ \).

If cease-release event \( \pi_i \) occurs then \( \Omega_i^+ \) is the point when \( \pi_i \)'s cease-release event \( \pi_i \) occurs, i.e., \( \Omega_i^+ = \ell_{\pi_i} \). Since \( \pi_i \) calls \( \text{doPromote}_i() \) only in line 46 (by inspection of Figure 16), it then follows that \( \Omega_i^+ = \ell_{\pi_i} = I_2^+ \).

**Proof of Part (m) if Part (a) for \( i \) is true:** As argued in Part (i), exactly one cease-release event among \( \pi_i \) and \( \theta_i \) occurs during \( \pi_i \)'s call to \( \text{doPromote}_i() \). If cease-release event \( \theta_i \) occurs then \( \Omega_i^+ \) is the point when \( \pi_i \)'s cease-release event \( \theta_i \) occurs, i.e, \( \Omega_i^+ = \ell_{\pi_i} \). Then \( \pi_i \) changes Ctr to 0 and the Ctr-cycle interval \( T \) ends at \( \Omega_i^+ = \ell_{\pi_i} = I_2^+ \).

If cease-release event \( \pi_i \) occurs then \( \Omega_i^+ \) is the point when \( \pi_i \)'s cease-release event \( \pi_i \) occurs, i.e., \( \Omega_i^+ = \ell_{\pi_i} \). Since \( \pi_i \) calls \( \text{doPromote}_i() \) only in line 46 (by inspection of Figure 16), it then follows that \( \Omega_i^+ = \ell_{\pi_i} = I_2^+ \).

Finally, we show that if Parts (a)-(m) are true for \( i \), then Part (a) is true for \( i+1 \), thus completing the proof. From Part (m) for \( i \), no \( \text{PawnSet.reset}() \) operation has been executed during \( [\Omega_i^-, \Omega_i^+] \). From Claim D.27(d), \( \Omega_i^+ = \Omega_{i+1}^- \). Then Part (m) for \( i+1 \) holds.

**Proof of (i):** From Claim D.27(a), \( \text{Sync1} = \text{Sync2} = \bot \) at \( \Omega_i^- = \gamma \). From Claims D.27(c) and D.27(d), it follows that \( \gamma = \Omega_i^- < \Omega_i^+ = \Omega_2^- < \Omega_2^+ = \Omega_3^- < \cdots < \Omega_{i-1}^- = \Omega_{i-1}^+ < \Omega_i^+ \).

From Claim D.27(c), for all \( t \in [\Omega_i^-, \Omega_i^+] \), \( R(t) \in \{P_i\} \). Then \( P_i \) has exclusive write-access to \( \text{Sync1} \) and \( \text{Sync2} \) throughout \( [\Omega_i^-, \Omega_i^+] \). Since \( P_i \) does not change Sync1 or Sync2 during \( [\Omega_i^-, \Omega_i^+] \) (Part (i)), then it follows that \( \text{Sync1} = \text{Sync2} = \bot \) throughout \( [\Omega_i^-, \Omega_i^+] = [\gamma, \Omega_i^+] \).

**Proof of (i):** As argued in Part (i), exactly one cease-release event among \( \pi_i \) and \( \theta_i \) occurs during \( \pi_i \)'s call to \( \text{doPromote}_i() \). If cease-release event \( \pi_i \) occurs then \( P_i \) promotes some process, and thus the number of processes that get promoted during \( T \) is larger than \( \ell \), which contradicts the definition of \( \ell \). Hence, cease-release event \( \theta_i \) occurs during \( \text{doPromote}_i() \) and \( \Omega_i^+ \) is the point when cease-release event \( \theta_i \) occurs, i.e, \( \Omega_i^+ = \ell_{\pi_i} \). Since \( \text{Ctr} \) is changed from 2 to 0 when \( \theta_i \) occurs, the Ctr-cycle interval \( T \) ends at \( \Omega_i^+ = \ell_{\pi_i} \), and thus \( I_2^+ = \Omega_i^+ = \ell_{\pi_i} \).
Case a - $\ell = 0$ : Consider the first \texttt{PawnSet.promote()} operation at $\gamma$. Since $\ell = 0$, the \texttt{PawnSet.promote()} operation at $\gamma$ returns value $(\bot, \bot)$. Then from Claim D.25[1], it follows that $B$’s cease-release event $\theta_B$ occurs at $t' = \theta_B^B \geq \gamma$, and throughout $[\gamma, t']$ no process is promoted, and for all $t \in [\gamma, t']$, $R(t) = \{B\}$. Since $\texttt{Ctr}$ is changed from 2 to 0 when $\theta_B$ occurs, the $\texttt{Ctr}$-cycle interval $T$ ends at $t' = \theta_B^B$, and thus $I_2^T = \theta_B^B = t'$. Then for all $t \in [\gamma, t'] = [\gamma, I_2^T]$, $|R(t)| = 1$.

From an inspection of Figure I.4 and the code, it follows that $B$ executed a \texttt{PawnSet.reset()} operation in line 67 during $[\gamma, t']$, and thus \texttt{PawnSet} is candidate-empty immediately after. Since for all $t \in [\gamma, t']$, $R(t) = \{B\}$, $B$ has exclusive registration-access to \texttt{PawnSet} throughout $[\gamma, t']$ (follows from Claim D.15). Then it follows that \texttt{PawnSet} is candidate-empty at $t' = I_2^T$.

Since for all $t \in [\gamma, t']$, $R(t) = \{B\}$, $B$ has exclusive write-access to $\texttt{Sync1}$ and $\texttt{Sync2}$ throughout $[\gamma, t']$ (follows from Claim D.15). Since $\texttt{Sync1} = \texttt{Sync2} = \bot$ at $\gamma$ (Claim D.25[1]), and $B$ does not write to $\texttt{Sync1}$ and $\texttt{Sync2}$ during $[\gamma, t']$, it follows that $\texttt{Sync1} = \texttt{Sync2} = \bot$ throughout $[\gamma, t'] = [\gamma, I_2^T]$.

Case b - $\ell \geq 1$ : From Part 1, $I_2^T = \Omega_{\ell}^T + \theta_B^B$. Then from Part 1, it follows that $\texttt{Sync1} = \texttt{Sync2} = \bot$ throughout $[\gamma, I_2^T]$, and from Claim D.27[1], it follows that for all $t \in [\Omega_{\ell - 1}, \Omega_{\ell}^T] = [I_2^T]$, $|R(t)| = 1$. Since $P_\ell$ ceases to be a releaser of L at $\Omega_{\ell}^T$, $R(I_2^T) = \emptyset$.

Since $\Omega_{\ell}^T = \theta_B^B$, $P_\ell$ executed line 68 and before that line 67. Hence, $P_\ell$ executed a \texttt{PawnSet.reset()} operation at $\theta_B^B < \Omega_{\ell}^T$. Since $\theta_B^B > \theta_y^B$ and $\theta_y^B > \Omega_{\ell}^T$ (by Part 2), it follows that $\theta_y^B > \Omega_{\ell}^T$. Hence, $P_\ell$ executed a \texttt{PawnSet.reset()} operation at $\theta_y^B \in [\Omega_{\ell - 1}, \Omega_{\ell}^T]$. Since $P_\ell$ is the only releaser of L throughout $[\Omega_{\ell - 1}, \Omega_{\ell}^T]$ (Claim D.27[2]), it follows from Claim D.15 that $P_\ell$ has exclusive registration-access to \texttt{PawnSet} throughout $[\Omega_{\ell - 1}, \Omega_{\ell}^T]$. Then it follows that \texttt{PawnSet} is candidate-empty at $\Omega_{\ell}^T = I_2^T$.

Claim D.29. $R(I_2^T) = \emptyset$ and at $I_2^T$, $\texttt{Sync1} = \texttt{Sync2} = \bot$ and \texttt{PawnSet} is candidate-empty for any $\texttt{Ctr}$-cycle interval $T$ during history $H$.

Proof. Let $T^k$ denote the $k$-th $\texttt{Ctr}$-cycle interval $T$ during history $H$. We give a proof by induction over the integer $k$. Basis - At $I_2^T$ for $T^1$, the claim holds trivially since all variables are at their initial values ($\texttt{Sync1} = \texttt{Sync2} = \bot$ and \texttt{PawnSet} is candidate-empty).

Induction Step - By the induction hypothesis, at $I_2^T$ for $T^{k-1}$, $R(I_2^T) = \emptyset$, and $\texttt{Sync1} = \texttt{Sync2} = \bot$ and \texttt{PawnSet} is candidate-empty. Since $T^k$ begins immediately after $T^{k-1}$ ends, to prove our claim we need to show that, when $T^{k-1}$ ends, there are no releasers of L and $\texttt{Sync1} = \texttt{Sync2} = \bot$ and \texttt{PawnSet} is candidate-empty. The time interval $T^{k-1}$ ends either at time $I_2^T$ or time $I_2^T$.

Case a - $T^{k-1}$ ends at time $I_2^T$: Then $I_2 = \emptyset$. From Claim D.23[1] it follows that $K$ is the only releaser of L during $I_1$. Since $I_2 = \emptyset$, it then follows from Claim D.23[1], that $K$’s $\texttt{Ctr.CAS}(1, 0)$ operation in line 36 is successful, and the interval $I_1$ as well as $T^{k-1}$ ends at time $\phi_K$. Then $K$’s cease-release event $\phi_K$ occurs at $\theta_B^B = \Omega_{\ell}^T$, and thus there are no releasers of L immediately after $T^{k-1}$ ends. And from Claim D.23[2], it follows that $\texttt{Sync1} = \texttt{Sync2} = \bot$ and \texttt{PawnSet} is candidate-empty when $T^{k-1}$ ends.

Case b - $T^{k-1}$ ends at time $I_2^T$: Then $I_2 \neq \emptyset$. Then our proof obligation follows immediately from Claim D.28[1].

Note that in the following claims, notations $I_0$, $I_1$, $I_2$, $\lambda, \gamma, \Omega_i$, $K$, $Q$ and $P_\ell$ are defined relative to a $\texttt{Ctr}$-cycle interval, as was defined previously in pages 13, 13 and 17. The exact $\texttt{Ctr}$-cycle interval is clear from the context of the discussion.

Lemma D.30. The mutual exclusion property holds during history $H$. 

52
Proof. For the purpose of a contradiction assume that at time $t$, two processes (say $p$ and $q$) are poised to execute a call to $L$.release(). From Claim [D.13][4], it follows that both $p$ and $q$ are releasers of $L$ at $t$. Consider theCtr-cycle interval $T$ such that $t \in T$.

From Claim [D.29] it follows that at $I_0^-$, Sync1 = Sync2 = $\perp$ and PawnSet is candidate-empty, and $R(I_0^-) = \emptyset$. Then from Claims [D.23][4], [D.23][1], [D.25][m], [D.25][m] and [D.25][k], it follows that during $T$, lock $L$ has two releasers only during $[I_2^-, \lambda]$. Then $t \in [I_2^-, \lambda)$. Also from Claim [D.25][m], for all $t \in [I_2^-, \lambda)$, $R(t) = [\mathcal{K}, \mathcal{Q}]$. Then $\{p, q\} = [\mathcal{K}, \mathcal{Q}]$. Let $p = \mathcal{K}$ and $q = \mathcal{Q}$ without loss of generality.

Recall that $I_2^-$ is the point in time when $\mathcal{Q}$ increases $\mathcal{Q}$ from 1 to 2 and sets $\text{Role}[\mathcal{Q}]$ to QUEEN in line 141. Since $q$’s call to lock() returned a non-$\perp$ value, it follows from an inspection of Figure 41 that $\mathcal{Q}$ returned either in line 177 or line 277. Then $\mathcal{Q}$ either read a non-$\perp$ value from Sync1 in line 141 or $\mathcal{Q}$ failed the Sync1.CAS($\perp$, $\infty$) operation in line 26. Since Sync1 = $\perp$ at $I_2^-$ (by Claim [D.24][m]), and $I_2^- = \frac{\mathbb{Q}}{\mathbb{Q}}$, it then follows that Sync1 is changed to a non-$\perp$ value during $[I_2^-, t]$. Clearly, $\mathcal{Q}$ does not change Sync1 during $[I_2^-, t]$. Hence, a contradiction.

Claim D.31. Consider an arbitrary $\mathcal{Q}$-cycle interval $T$.

(a) If $p$ is collected during $T$ and $p$ does not abort, then $p$ is promoted and notified during $T$.

(b) If $\text{apply}[p] = (\text{REG}, s)$ at $I_0^-$, where $s \in \mathbb{N}$, and $p$ does not abort and $p$ does not increase $\mathcal{Q}$, then $p$ is notified during $T$.

Proof. Proof of (a): From Claim [D.29] it follows that at $I_0^-$, Sync1 = Sync2 = $\perp$ and PawnSet is candidate-empty, and $R(I_0^-) = \emptyset$. Then from Claim [D.25][m], it follows that exactly one call to doCollect() is executed during $T$ by a process $q \in \{\mathcal{K}, \mathcal{Q}\}$. Since processes are collected only during a call to doCollect($\mathcal{Q}$), $q \in \{\mathcal{K}, \mathcal{Q}\}$ collects $p$ during doCollect($\mathcal{Q}$) during $T$. And $q$ does so by executing a PawnSet.collect($A$) operation in line 55, where $A[p] = s \in \mathbb{N}$, and sets the $p$-th entry of PawnSet to (REG, $s$). Since a PawnSet.promote() that returns ($\perp$, $\perp$, $\perp$) is executed at $A[p]$ during $T$, it then follows from the semantics of the PawnSet object that $p$ was promoted during $T$. Then $p = \mathcal{P}_i$, for some $i \leq \ell$. Note that $T$ does not end during $[\Omega_i^-, \Omega_i^+]$.

We now show that $p$ is also notified of its promotion during $T$. The process (say $r$) that promoted $p$ by executing a PawnSet.promote() operation in line 65 also goes on to notify $p$ of its promotion by executing a apply[p].CAS((REG, $s$), (PRO, $s$)) operation in line 70. Since $p$ does not abort, it follows from an inspection of Figure 147 and the code, that $p$ spins on apply[p] in line 17 until its notification. Then $p$ executes line 97 at $t_9 > t_7 > t_6$ = $\Omega_i^-$. Since $t_9 > \Omega_i^-$ and $T$ does not end before $\Omega_i^+$, it follows that $p$ is notified during $T$.

Proof of (b): Since $p$ does not increase $\mathcal{Q}$ it follows that $p$ reads $\mathcal{Q} = 2$ every time it executes a Ctr.inc() operation in line 55 and sets $\text{Role}[\mathcal{Q}] = \text{PAWN}$ in line 55. Then $p$ satisfies the if-condition of line 60 and spins on variables apply[p] and Ctr in line 77. Since Ctr is only changed to 0 at the end of $T$, it follows that Ctr = 2 throughout $[I_2^-, I_2^+]$. Then $p$ busy-waits in the spin loop of line 17 until the end of $T$, or if it reads value (PRO, $s$), for some $s \in \mathbb{N}$, from apply[p] in line 77 during $T$. Now, apply[p] is changed to value (PRO, $s$) by some process other than $p$, only if that process notifies $p$, i.e., executes a successful apply[p].CAS((REG, $s$), (PRO, $s$)) operation in line 70. We now show that $p$ is notified during $T$.

53
From Claim [D.29] it follows that at \( I_0 \), Sync1 = Sync2 = \perp and PawnSet is candidate-empty, and \( R(I_0) = \emptyset \). Then from Claim [D.25][3], it follows that exactly one call to doCollect() is executed during \( T \) by a process \( q \in \{ K, Q \} \). Consider the point when \( q \) reads \( \text{apply}[p] \) in line 52. If \( q \) reads a value different from \( (\text{REG}, s) \), then some process must have notified \( p \) during \([p_q, t_q^2] \), and since \( I_0 < t_p^1 \) and \( t_q^2 \in T \), our claim holds. If \( q \) reads the value \( (\text{REG}, s) \) from \( \text{apply}[p] \), then \( q \) collects \( p \) during \( T \) by executing a PawnSet.collect(\( A \)) operation, where \( A[p] = s \), in line 55 during \( T \). Thus, our claim follows from Part (a).

**Claim D.32.** If \( p \) registered itself in line 2 and incurred \( O(1) \) RMRs in the process, and \( p \) does not abort, and all processes in the system continue to take steps, then

(a) \( p \) finishes its call to lock\(_p\)() and returns a non-\( \perp \) value.

(b) \( p \) incurs \( O(1) \) RMRs in expectation during its call to lock\(_p\)().

**Proof.** Proof of (a) and (b): From an inspection of the code of lock\(_p\)(), \( p \) incurs a constant number of RMRs while executing all other lines of lock\(_p\)() except while busy-waiting in lines 2, 7, and 14.

Consider \( p \)'s call to lock\(_p\)(). By assumption of the claim, \( p \) registered itself in line 2 by executing a successful apply\([p]\).CAS(\langle 0, 0, 0 \rangle, (\text{REG}, s)) operation in line 2 and incurred \( O(1) \) RMRs in the process. Then \( p \) proceeds to execute a Ctr.inc() operation in line 5 and stores the returned value in Role\([p]\). A Ctr.inc() operation returns values in \{KING, QUEEN, PAWN, \perp\}. If it returns \perp, \( p \) repeats the role-loop, and executes another Ctr.inc() operation in line 5. From Claim A.2, it follows that \( p \) repeats the role-loop only a constant number of times before its Ctr.inc() operation returns a non-\perp value.

**Case a -** \( p \) executes a Ctr.inc() operation in line 5 that returns KING. Then \( p \) sets Role\([p]\) = KING in line 5. Then from the code structure \( p \) does not busy-wait on any variables, and proceeds to return \( \infty \) in line 17, and thus incurs only \( O(1) \) RMRs. Hence, (a) and (b) hold.

**Case b -** \( p \) executes a Ctr.inc() operation in line 5 that returns QUEEN. Then \( p \) increments Ctr from 1 to 2 in line 5 and sets Role\([p]\) = QUEEN in line 5. Then from the code structure \( p \) proceeds to busy-wait on Sync1 in line 14. Since \( p \) increased Ctr from 1 to 2, \( I_1^p = I_2^p \) for some Ctr-cycle interval \( T \). From Claim D.29 it follows that at \( I_0^p \), Sync1 = Sync2 = \perp and PawnSet is candidate-empty, and \( R(I_0^p) = \emptyset \). Then from Claim D.24[3] it follows that \( p \) does not starve in line 14. Since \( p \) does not abort, it follows from an inspection of Figure 10 and the code, that \( p \) returns a non-\perp value in line 14, and \( p \) does not change Sync1. Hence, we have shown that Part (a) holds. Apart from \( p \), the only releasers of L during \( T \) are \{K, \( P_1, \ldots, P_\ell \} \}, where \( \ell \) is the number of promotions during \( T \). From an inspection of Figures 8, 9, 15, 16 and the code, it follows that only \( K \) possibly writes a non-\perp value to Sync1 during \( T \) in line 37. Since Sync1 is written to only be a releaser of L, and \( I_1^p \in T \), it then follows that Sync1 is changed to a non-\perp value at most once during \( T \). Then \( p \) incurs at most one RMR while busy-waiting on Sync1. Hence, we have shown that Part (b) holds.

**Case c -** \( p \) executes a Ctr.inc() operation in line 5 that returns PAWN. Then \( p \) found Ctr to be 2 in line 5 and set Role\([p]\) = PAWN in line 5. Then from the code structure \( p \) proceeds to busy-wait on apply\([p]\) and Ctr in line 7.

We now show that \( p \) does not starve while busy-waiting in line 7. Since Ctr = 2 at \( I_0^p \), it follows that \( I_5^p \in T \) for some Ctr-cycle interval \( T \).

**Subcase (i) -** apply\([p]\) = \( (\text{REG}, s) \) at \( I_0^p \) during \( T \), for some \( s \in \mathbb{N} \). Then from Claim D.31[i], \( p \) is notified during \( T \). Since \( p \) is notified during \( T \) and \( p \) does not abort, it follows that \( p \) does
not change $\text{apply}[p]$, and thus $\text{apply}[p]$ is changed from $\langle \text{REG}, s \rangle$ to $\langle \text{PRO}, s \rangle$ when $p$ is notified. Since $\text{apply}[p]$ is changed from $\langle \text{PRO}, s \rangle$ to some other value only by $p$, it then follows that $\text{apply}[p]$ remains $\langle \text{PRO}, s \rangle$ when $p$ reads $\text{apply}[p]$ for the first time after $p$ was notified. Then $p$ incurs one RMR when it reads $\text{apply}[p]$ in line 7 after its notification, breaks out of the spin loop of line 4, proceeds to satisfy the if-condition of line 8, and sets $\text{Role}[p] = \text{PAWN}_p$ in line 9, and proceeds to return $\infty$ in line 17. Then we have shown Parts (a) and (b) hold.

Subcase (ii) - $\text{apply}[p] \neq \langle \text{REG}, s \rangle$ at $I_0^-$ during $T$, for some $s \in \mathbb{N}$. Consider the only call to $\text{doCollect}()$ during $T$ by $q \in \{K, Q\}$. If $p$ registered itself (i.e., executed its $\text{apply}[p].\text{CAS}((\bot, \bot), \langle \text{REG}, s \rangle)$ operation in line 2) before $q$ reads $\text{apply}[p]$ in line 52 during $\text{doCollect}_q()$, then $q$ collects $p$ during $T$. Then from Claim D.31(b), $p$ is collected, promoted during $T$, and eventually notified. Then Parts (a) and (b) hold as argued in Subcase (i).

If $p$ registers itself after $q$ attempts to acknowledge $p$ during $T$, then no process changes $\text{apply}[p]$ during $T$. Then $p$ continues to busy-wait in line 7 until the Ctr-cycle interval $T$ ends and Ctr is reset to 0.

If Ctr is increased to 2 before $p$ reads Ctr again in line 7, then let $T'$ be the Ctr-cycle interval that starts when Ctr was reset to 0 at the end of $T$. Since $\text{apply}[p]$ was changed to a non-$\langle \text{REG}, s \rangle$ value before the start of $T'$, it follows that $\text{apply}[p] = \langle \text{REG}, s \rangle$ at the start of $T'$. Then from Claim D.31(b), $p$ is acknowledged, collected, promoted during $T'$, and eventually notified. Then Parts (a) and (b) hold as argued in Subcase (i).

If Ctr $\neq 2$ when $p$ reads Ctr again in line 7, then $p$ incurs one RMR in line 7 breaks out of the spin loop, and proceeds to execute line 8. If $p$ satisfies the if-condition of line 8 then $p$ has been acknowledged during some Ctr-cycle interval $T''$. Then from Claim D.31(b), $p$ is collected, promoted during $T''$, and eventually notified. Then Parts (a) and (b) hold as argued in Subcase (i). If $p$ fails the if-condition of line 8 then $p$ proceeds to repeat the role-loop. Consider $p$'s second iteration of the role-loop. If $p$ sets $\text{Role}[p] = \{\text{KING, QUEEN}\}$ in line 3 then Parts (a) and (b) hold as argued in Case a and Case b. If $p$ sets $\text{Role}[p] = \text{PAWN}$ in line 5 then it follows that $t_p \in T''$, for some Ctr-cycle interval $T'''$, such that $\text{apply}[p] = \langle \text{REG}, s \rangle$ at $I_0^-$ for $T'''$. Parts (a) and (b) hold as argued in Case c(i). \hfill \square

**Lemma D.33.** If all processes in the system continue to take steps and $p$ does not abort, then

(a) $p$ finishes its call to $\text{lock}_p()$ and returns a non-$\bot$ value.

(b) $p$ incurs $O(1)$ RMRs in expectation during its call to $\text{lock}_p()$.

**Proof.** From an inspection of $\text{lock}_p()$, $p$ incurs a constant number of RMRs while executing all other lines of $\text{lock}_p()$ except while busy-waiting in lines 2, 7, and 14.

Consider $p$'s call to $\text{lock}_p()$. Process $p$ first attempts to register itself in line 2 by attempting to execute an $\text{apply}[p].\text{CAS}((\bot, \bot), \langle \text{REG}, s \rangle)$ operation. Now, $\text{apply}[p]$ is changed from $\langle \bot, \bot \rangle$ to a non-$\langle \bot, \bot \rangle$ value only by $p$ (Claim D.6[3]). If $\text{apply}[p] = \langle \bot, \bot \rangle$ at $t_p^-$, then $p$ executes a successful $\text{apply}[p].\text{CAS}((\bot, \bot), \langle \text{REG}, s \rangle)$ operation in line 2 and incurs only one RMR. Then our claims follow immediately from Claims D.32[3] and D.32[4].

If $\text{apply}[p] \neq \langle \bot, \bot \rangle$ at $t_p^-$, it follows that some process $p'$ executed a successful $\text{apply}[p].\text{CAS}((\bot, \bot), \langle \text{REG}, s' \rangle)$ in line 2 during $\text{lock}_p()$, and $\text{apply}[p] \neq \langle \bot, \bot \rangle$ throughout $[t_p^- \ldots t_p^+]$. Since calls to $\text{lock}_p()$ are not executed concurrently, it follows that $p'$ has completed its call to $\text{lock}_p()$ during $[t_p^- \ldots t_p^+]$.

**Case 1** - $p'$'s call to $\text{lock}_p()$ returned $\bot$. Then it follows from the code structure that $p'$ executed a call to $\text{abort}_p()$ and returned from line 18 or 33. Since $p$ executed a successful
apply\[p,\text{CAS}(\perp, \perp, (\text{REG}, s'))\] in line 2, \(p'\) could not have aborted while busy-waiting on line 2 and thus \(p'\) aborted while busy-waiting in line 7 or 14. Then \(p'\) executed line 3 and set its local variable \(p'.\text{flag}\) to \text{true}, and thus \(p\) could not have returned \(\perp\) from line 13 during \text{abort}\(_p()\). Then \(p'\) returned \(\perp\) in line 33 and thus \(p'\) executed operations \(\text{apply}[p,\text{CAS}(\langle \perp, \perp \rangle, (\text{REG}, s'))\] (in line 19), and \(\text{apply}[p,\text{CAS}(\langle \text{PRO}, s', \perp, \perp \rangle)\] (in line 32). Since, \(\text{apply}[p]\) can be changed from \(\langle \text{REG}, s' \rangle\) only to \(\langle \text{PRO}, s' \rangle\), and from \(\langle \text{PRO}, s' \rangle\) only to \(\langle \perp, \perp \rangle\), it then follows that \(p'\) executes a successful \(\text{apply}[p,\text{CAS}(\langle \text{PRO}, s', \perp, \perp \rangle)\] (in line 32). Then \(p'\) eventually resets \(\text{apply}[p]\) during its \text{lock}_p() call. Since \(\text{apply}[p] \neq \langle \perp, \perp \rangle\) throughout \(\langle \perp, \perp \rangle\) and \(p'\) completed its call to \text{lock}_p() during \(\langle \perp, \perp \rangle\), we have a contradiction.

\textbf{Case 2} - \(p'\)'s call to \text{lock}_p() returned a non-\(\perp\) value. Then from the code structure \(p'\) executed operations \(\text{apply}[p,\text{CAS}(\langle \text{REG}, s', \langle \text{PRO}, s' \rangle)\] (in line 16 or line 19) before returning from its call to \text{lock}_p(). Since \(\text{apply}[p]\) can be changed from \(\langle \text{REG}, s' \rangle\) only to \(\langle \text{PRO}, s' \rangle\), and from \(\langle \text{PRO}, s' \rangle\) only to \(\langle \perp, \perp \rangle\) and only by a process with pseudo-ID \(p\), it then follows that \(\text{apply}[p] = \langle \text{PRO}, s' \rangle\) when \(p'\)’s \text{lock}_p() returns. Then it also follows that \(\text{apply}[p] = \langle \text{PRO}, s' \rangle\) until a process with pseudo-ID \(p\) executes an \(\text{apply}[p,\text{CAS}(\langle \text{PRO}, s', \perp, \perp \rangle)\] operation.

Since \(p'\) won the lock \(L\), it follows that some process, say \(r\), eventually executes a call to \text{release}\(_p(j), for some integer \(j\). Since a call to \text{release}\(_p(j)\) is wait-free and all processes continue to take steps, it follows that eventually \(r\) executes lines 18 and 19 where it reads value \(\langle \text{PRO}, s' \rangle\) from \(\text{apply}[p]\) in line 18 and resets \(\text{apply}[p]\) with a \(\text{apply}[p,\text{CAS}(\langle \text{PRO}, s', \perp, \perp \rangle)\] operation in line 19. Since \(p\) does not abort, and no other process calls \text{lock}_p() concurrently, it then follows that eventually \(p\) executes a successful \(\text{apply}[p,\text{CAS}(\langle \perp, \perp \rangle, (\text{REG}, s'))\] operation in line 2. Since \(\text{apply}[p]\) changed only once from \(\langle \text{PRO}, s' \rangle\) to \(\langle \perp, \perp \rangle\) while \(p\) busy-waited in line 2 it follows that \(p\) incurs \(O(1)\) RMRs during the entire process. Then our claims follow immediately from Claims \(D.32[31]\) and \(D.32[5]\).

\textbf{Lemma D.34.} The abort-way is wait-free.

\textit{Proof.} The abort-way is defined to be all steps taken by a process (say \(p\)) after it receives a signal to abort and breaks out of one of the busy-wait cycles of lines 2, 7 or 14. After \(p\) breaks out of one of the busy-wait cycles of lines 2, 7 or 14 \(p\) executes a call to \text{abort}\(_p()\). If \(p'\)'s call to \text{abort}\(_p()\) returns \(\perp\), then \(p'\)'s passage ends, or else \(p'\)’s \text{lock}_p() returns a non-\(\perp\) value and \(p\) calls \text{release}_p() and \(p'\)'s passage ends when the \text{release}_p() method returns. Since \text{abort}_p() and \text{release}_p() are both wait-free (by Lemma \(D.2\)), our claim follows.

\textbf{Lemma D.35.} The starvation freedom property holds during history \(H\).

\textit{Proof.} Consider a process \(p\) that begins to execute its passage. From Lemma \(D.33[31]\), it follows that if \(p\) does not abort during \text{lock}_p() and all processes continue to take steps then \(p\) eventually returns from \text{lock}_p() with a non-\(\perp\) value. Then \(p\) eventually calls \text{release}_p(), and since \text{release}_p() is wait-free, \(p\) eventually completes its passage. If \(p\) receives a signal to abort during \text{lock}_p(), then \(p\) executes its abort-way. Since the abort-way is wait-free (by Lemma \(D.34\)), \(p\) eventually completes its passage.

\textbf{Lemma D.36.} If a call to \text{release}_p(j) returns \text{true}, then there exists a concurrent call to \text{lock()} that eventually returns \(j\).

\textit{Proof.} The only operations that write a value to \text{Sync}1 are \text{Sync1.CAS}(\perp, \infty) in line 26 and \text{Sync1.CAS}(\perp, j) in line 37. From Claim \(D.15\) \text{Sync}1 is written only by a releaser of \(L\). From Claim \(D.29\) it follows that at \(I_0\), \text{Sync1} = \text{Sync2} = \perp and \text{PawnSet} is candidate-empty, and \(R(I_0) = \emptyset\). Then from Claims \(D.28[31], D.28[0], D.25[41], D.25[40], D.25[4]\) and \(D.28[4]\), the only
releasers of $L$ during a $\text{Ctr}$-cycle interval $T$, are $\{K, Q, P_1, \ldots, P_t\}$. Then from an inspection of Figures 8, 9, 10, 11 and 16 it follows that only $K$ and $Q$ can write to $\text{Sync1}$ during $\text{Ctr}$-cycle interval $T$.

Since $p$ returns $\text{true}$, it then follows from an inspection of the code that $p$ executed a successful $\text{Sync1.CAS}(\perp, j)$ operation in line 57, and thus failed the $\text{Ctr.CAS}(1, 0)$ operation in line 58 and $\text{Role}[p] = \text{KING}$ at $t_{36}$. Then $p = K$ for some $\text{Ctr}$-cycle interval $T$. Since $K$ failed the $\text{Ctr.CAS}(1, 0)$ operation in line 36, it then follows that $\text{Ctr}$ was increased to 1 by process $Q$ during $T$, and $I_2^Q = t_{36} < t_{36}$. Since $I_1^Q = t_{36}$ and $I_1^Q < I_2^Q$, it then follows that $Q$'s $\text{lock}_Q()$ call is concurrent to $K$'s $\text{release}_K(j)$ call.

From Claim D.29 it follows that at $I_0^Q$, $\text{Sync1} = \text{Sync2} = \perp$ and $\text{PawnSet}$ is candidate-empty, and $R(I_0^Q) = \emptyset$. Then from Claim D.25(a), $\text{Sync1} = \perp$ at $I_2^Q$, and $K$ and $Q$ are the only two releasers of $L$ during $[I_2^Q, \lambda]$, where $\lambda$ is the first point in time when $T$ is changed to a non-$\perp$ value, and $\lambda = \min(I_2^Q, t_{56})$.

Now, $\text{Sync1}$ is reset only in line 58 and since $t_{58} > t_{56} \geq \lambda$ and $t_{58} > t_{56} \geq \lambda$, it then follows that $K$ and $Q$ do not reset $\text{Sync1}$ during $[I_2^Q, \lambda]$. Since $K$ and $Q$ are the only processes with write-access to $\text{Sync1}$, $\text{Sync1}$ is not reset during $[I_2^Q, \lambda]$.

Consider $Q$'s $\text{lock}()$ call (see Figure 10). Since $K$ executed a successful $\text{Sync1.CAS}(\perp, j)$ operation and $\text{Sync1}$ is not reset during $[I_2^Q, \lambda]$, it then follows that if $Q$ executes the $\text{Sync1.CAS}(\perp, \infty)$ operation in line 26 then the operation fails. From an inspection of Figure 10 $Q$ either returns from its $\text{lock}()$ call in line 17 or line 27. In both these lines, $Q$ returns the non-$\perp$ value stored in $\text{Sync1}$. Since $K$ is the only process apart from $Q$ that can write to $\text{Sync1}$ $Q$ returns the value $j$ that $K$ wrote during its $\text{release}_K(j)$ call.

Now consider an implementation of object $\text{ALockArray}_N$, where instance $\text{PawnSet}$ is implemented using object $\text{SFMSUnivConst}(\text{AbortableProArray}_n)$, and the operations in lines 55, 61, 65, 64 and 67 are executed using the $\text{doFast}()$ method, while the operation in line 24 is executed using the $\text{doSlow}()$.

**Claim D.37.** Lines 64, 65, 67 of $\text{doPromote}()$, all lines of $\text{doCollect}()$, and lines 57, 62 are not executed concurrently.

**Proof.** From Claim D.13(b), it follows that only a releaser of $L$ can execute any of these lines. From Claim D.29 it follows that at $I_0^Q$, $\text{Sync1} = \text{Sync2} = \perp$ and $\text{PawnSet}$ is candidate-empty, and $R(I_0^Q) = \emptyset$. Then from Claims D.23(a), D.23(f), D.25(a), D.25(e), D.28(k), and D.28(l) it follows that $L$ has more than one releaser only during $[I_2^Q, \lambda]$ for some $\text{Ctr}$-cycle interval $T$. More specifically, there are two releasers of $L$ only during $[I_2^Q, \lambda]$, and the releasers are $K$ and $Q$. From Claim D.25(k) it follows that a $\text{doCollect}()$ is executed only by $K$ or $Q$ but not both. Then it follows immediately that lines of $\text{doCollect}()$ are not executed concurrently. Since $\lambda = \min(I_2^Q, t_{56})$, it follows from an inspection of Figures 8, 9, 10, 11 and 12 and the code, that processes $K$ and $Q$ have not executed a call to $\text{doPromote}()$ or lines 57, 62 of $\text{helpRelease}()$, before $t_{56}$, and $t_{56}$ respectively. Then none of the lines chosen in the claim are executed concurrently, and thus our claim holds.

**Lemma D.38.** (a) Both $\text{helpRelease}_p()$ and $\text{doPromote}_p()$ have $O(1)$ RMR complexity.

(b) $\text{doCollect}_p()$ has $O(n)$ RMR complexity.

(c) $\text{abort}_p()$ has $O(n)$ RMR complexity.

(d) If a call to $\text{release}_p(j)$ returns $\text{true}$, then $p$ incurs $O(n)$ RMRs during $\text{release}_p(j)$.  

57
(e) If a call to \(\text{release}_p(j)\) returns false, then \(p\) incurs \(\mathcal{O}(1)\) RMRs during \(\text{release}_p(j)\).

Proof. Proof of (a) and (b): As per the properties of object SFMSUnivConst\(\langle\text{AbortableProArray}_n\rangle\) (Lemma 2.2), an operation performed using the doFast() method has \(\mathcal{O}(1)\) RMR complexity, as long as it is not executed concurrently with another doFast() method call. Since PawnSet is an instance of object SFMSUnivConst\(\langle\text{AbortableProArray}_n\rangle\), where operations in lines 25, 61, 65, 63 and 67 are executed using the doFast() method, and each of these operations are not executed concurrently (by Claim D.37), it then follows that all of these operations have \(\mathcal{O}(1)\) RMR complexity. Then Part (a) follows immediately from an inspection of methods helpRelease() and doPromote(). Since method doCollect() has a loop of size \(n\) that incurs a constant number of RMRs in each iteration, Part (b) follows.

Proof of (c), (d) and (e): As per the properties of object SFMSUnivConst\(\langle\text{AbortableProArray}_n\rangle\) (Lemma 2.2), an operation performed using the doSlow() method has \(\mathcal{O}(n)\) RMR complexity, where \(n\) is the maximum number of processes that can access the object concurrently. Since the operation in line 21 is executed using the doSlow() method, the operation has \(\mathcal{O}(n)\) RMR complexity. Since helpRelease() and doPromote() have an RMR complexity of \(\mathcal{O}(1)\) (by Part (a), and doCollect() has an RMR complexity of \(\mathcal{O}(n)\) (by Part (b)), it then follows from an inspection of abort(), that a call to abort() has an RMR complexity of \(\mathcal{O}(n)\). Thus Part (e) follows.

If a call to \(\text{release}_p(j)\) returns true, then \(p\) does execute a call to doCollect\(_p()\) in line 38, else it does not. Then from an inspection of release\(_p(j)\), Parts (d) and (c) follow immediately. \(\square\)

E The Tree Based Randomized Abortable Lock

E.1 Implementation / Low Level Description

We assume that the tree structure \(T\) provides a function \(\text{getNode}()\), such that, for a leaf node \(\text{leaf}\) and integer \(\ell\), the function \(\text{getNode}(\text{leaf}, \ell)\) returns a pair \((u, i)\), where \(u\) is the \(\ell\)-th node on the path from \(\text{leaf}\) to the root node, and \(i\) is the index of the child node of \(u\) that lies on the path.

We now describe the implementation of the abortable lock (see Figure 17).

Description of the \(\text{lock}_p()\) method. Suppose process \(p\) executes a call to \(\text{lock}_p()\). With every iteration of the while-loop, process \(p\) captures at least one node on its path from \(\text{leaf}_p\) to \(T.\text{root}\). Suppose \(p\) executes an iteration of while-loop (lines 11-10) and \(\ell_p = k\) at line 11 for some arbitrary integer \(k\). In line 2 process \(p\) determines the \(k\)-th node (say \(u\)) on \(p.\text{path}\) and the index (say \(r\)) of \(u\)'s child node that lies on \(p.\text{path}\), and stores them in local variables \(v_p\) and \(i_p\). The variables \(v_p\) and \(i_p\) are unchanged during the rest of the iteration. In line 3 process \(p\) attempts to capture \(u.\text{L}\), and thus node \(u\) by executing a call to \(u.\text{L}.\text{lock}()\) with pseudo-ID \(r\). If \(p\)'s \(u.\text{L}.\text{lock}\()\) returns an integer value (say \(j\)) then \(p\) has been transferred all nodes on its path up to height \(j\) (we ensure \(j \geq h_u\)). If \(p\)'s \(u.\text{L}.\text{lock}()\) returns \(\infty\) then \(p\) has captured lock \(u.\text{L}\) in lines 4 and 5 \(p\) stores the height of the highest captured node in its local variable \(\ell_p\). In line 6 \(p\) checks whether it has received a signal to abort. In this case \(p\) releases all its captured nodes by executing a call to \(\text{release}_p()\) in line 7 and then returns from its call to \(\text{lock}_p()\) in line 8 with value \(\bot\). Otherwise \(p\) continues its while-loop. On completing its while-loop, \(p\) owns the root node, and thus returns with value \(\infty\) in line 11 to indicate a successful \(\text{lock}()\) call.

Description of the \(\text{release}_p()\) method. Suppose process \(p\) executes a call to \(\text{release}_p()\). Let \(s\) be the highest node \(p\) owns at the beginning of \(\text{release}_p()\). We later prove that \(h_s = \ell_p\).
Algorithm: Implementation of the abortable lock

\begin{verbatim}
define Node: struct { L: ALockArray_ \Delta } 
shared: \ T: complete \Delta-ary tree of height \Delta and node type Node 
local: v: Node init ⊥; i, ℓ, k: int init 0; abort_signal: boolean init false;

define function \ T.getNode(Node leaf, int ℓ): returns a pair ⟨u, i⟩, where u is the ℓ-th node on the path from leaf to the root node of \ T, and i is the index of the child node of u that lies on the path.

Method lock_p()

\begin{verbatim}
while ℓ < \ T.height do
  (v, i) ← \ T.getNode(leaf, ℓ + 1)
  val ← v.L.lock_i()
  if val = ∞ then ℓ ← ℓ + 1
  if val \notin \{⊥, ∞\} then ℓ ← val
  if abort_signal = true then
    release_p()
    return ⊥
  end
end
return ∞
\end{verbatim}

Method release_p()

\begin{verbatim}
while k ≤ ℓ do
  (v, i) ← \ T.getNode(leaf, k)
  if v.L.release_i(ℓ) then
    break
  end
  k ← k + 1 end
\end{verbatim}

Figure 17: Implementation of the abortable lock
During an iteration of the while-loop (lines 12-16), process $p$ either releases a node on its path from leaf$_p$ to $s$, or $p$ hands over all remaining nodes that it owns to some process.

Consider the execution of an iteration of the while-loop where $k_p = t$ at line 12 for some integer $t \leq h_s$. In line 13 process $p$ determines the $t$-th node (say $u$) on path$_p$ and the index (say $r$) of $u$’s child node that lies on path$_p$, and stores them in local variables $v_p$ and $i_p$. In line 14 process $p$ releases $u.L$ and thus node $u$, by executing a call to $u.L.release(h_u)$ with pseudo-ID $r$. If $p$’s $u.L.release_r(h_u)$ returns false then $p$ has successfully released lock $u.L$, and thus node $u$. If $p$’s $u.L.release_r(h_u)$ returns true then $p$ has successfully handed over all nodes from $u$ to $s$ on path$_p$ to some process that is executing a concurrent call to $u.L.lock()$. If $p$ has handed over all its nodes, then $p$ breaks out of the while-loop in line 14 and returns from its call to $\text{release}_p()$. If $p$ has not handed over all its nodes then $p$ increases $k_p$ in line 15 and continues its while-loop.

Notice that our strategy to release node locks is to climb up the tree until all node locks are released or a hand over of remaining locks is made. Climbing up the tree is necessary (as opposed to climbing down) in order to hand over node locks to a process, say $q$, such that the handed over nodes lie on path$_q$. There is however a side effect of this strategy which is as follows: Suppose $p$ owns nodes $v$ and $u$ on path$_p$ such that $\langle u, i \rangle = \text{getNode}(\text{leaf}_p, h_u)$ and $v$ is the $i$-th child on node $u$. Now suppose $p$ releases lock $v.L$ at node $v$. Since the lock at node $v$ is now released, some process $r \neq p$ may now capture lock $v.L$ and then proceed to call $u.L.lock()$. If process $p$ has not yet released $u.L$ by completing its call to $u.L.release()$, then we have a situation where a call to $u.L.lock()$ is made before a call to $u.L.release()$ is completed. Since there can be at most one owner of lock $v.L$ there can be at most one such call to $u.L.lock_i()$ concurrent to $u.L.release_i()$. This is precisely the reason why we designed object $\text{ALockArray}_n$ to be accessed by at most $n + 1$ processes concurrently.

### E.2 Analysis and Proofs of Correctness

In this section, we formally prove all properties of our abortable lock for the CC model. We first, establish the safety conditions on the usage of the object.

**Condition E.1.** (a) If process $p$ executes a successful $\text{lock}_p()$ call, then process $p$ eventually executes a $\text{release}_p()$ call.

(b) A process calls method $\text{release}()$ if and only if its last access of the lock object was a successful $\text{lock}()$ call.

(c) Methods $\text{lock}_p()$ and $\text{release}_p()$ are called only by process $p$, where $p \in \{0, \ldots, N - 1\}$.

(d) For every $\text{release}_p()$ call, there must exist a unique successful $\text{lock}_p()$ call that has been executed.

**Notations and Definitions.** Let $H$ be an arbitrary history of an algorithm that accesses an instance $L$ of our abortable lock where Condition E.1 is satisfied. Consider an arbitrary node $u$ on the tree $T$. Let $h_u$ denote the height of node $u$.

A node $u$ is said to be handed over from process $p$ to process $q$, when $p$ executes a $v.L.release(j)$ call that returns true, where $j \geq h_u > h_u$, and $q$ executes a concurrent $v.L.lock()$ call that returns $j$. Process $p$ is said to start to own node $u$ when $p$ captures $u.L$ or when it is handed over node $u$ from the previous owner of node $u$. Process $p$ ceases to own node $u$ when $p$ releases $u.L$, or when $p$ hands over node $u$ to some other process.

**Claim E.2.** Consider an arbitrary process $p$ and some node $u$ on path$_p$. 

(a) If \( p \) executes a \texttt{u.L.lock}() operation that returns value \( j \notin \{\bot, \infty\} \), then \( j \geq h_u \).

(b) The value of \( \ell_p \) is increased every time \( p \) writes to it.

(c) If \( \ell_p = k \), then process \( p \) owns all nodes on \texttt{path}_p \) up to height \( k \).

\textbf{Proof of (a)}: Then from the properties of object \texttt{ALockArray} (Lemma 3.1), it follows that some process (say \( q \)) executed a concurrent \texttt{u.L.release}(\( j \)) operation. Then from the code structure, \( q \) executed a \texttt{u.L.getNode}(\( \text{leaf}_q, k \)) operation in line 13 that returned \( \langle u, i \rangle \), for some \( i \), such that \( h_u = k_q \) (from the semantics of the \texttt{getNode}() method). Since \( j = \ell_q \geq k_q = h_u \), our claim follows.

\textbf{Proof of (b)}: Process \( p \) writes to its local variable \( \ell_p \) only in lines 4 and 5. Clearly, \( p \) increases \( \ell_p \) every time it executes line 4. Now, suppose \( p \) executes line 5 where it writes the value of \( \text{val}_p \) to \( \ell_p \), where \( \text{val}_p = u, \) for some node \( u \). Since \( p \) satisfies the if-condition of line 5 and the \texttt{ALockArray} method \texttt{lock()} only returns a value in \( \{\bot, \infty\} \cup \mathbb{N} \), it follows that \( p \)'s call to \texttt{u.L.lock()} returned a non-\(\{\bot, \infty\} \) value. Then from Part (a), \( \text{val}_p \geq h_u \). Since \( p \) also executed a \texttt{T.getNode}(\( \text{leaf}_p, b \)) operation in line 2 where \( b = \ell_p + 1 \) that returned \( \langle u, i \rangle \), for some \( i \), such that \( h_u = b \) (from the semantics of the \texttt{getNode}() method), it follows that \( \text{val}_p \geq h_u = \ell_p + 1 \). Then, \( p \) increases \( \ell_p \) when \( p \) writes \( \text{val}_p \) to \( \ell_p \) in line 5.

\textbf{Proof of (c)}: Let \( t_i \) be the point in time such that \( p \) writes to its local variable \( \ell_p \) for the \( i \)-th time. We prove our claim by induction over \( i \).

\textbf{Basis (}i = 0\textbf{)}: Since the initial value of \( \ell_p \) is 0 and \( \ell_p \) is written to for the first time only at \( t_1 \geq t_0 \), the claim holds.

\textbf{Induction step (}i > 0\textbf{)}: Let the value of \( \ell_p \) be \( j \) after the \( (i - 1) \)-th write to it. Then from the induction hypothesis, \( p \) owns all nodes on \texttt{path}_p \) up to height \( j \). Consider the iteration of the while-loop during which \( p \) writes to \( \ell_p \) for the \( i \)-th time, and specifically the \texttt{T.getNode}(\( \text{leaf}_p, \ell + 1 \)) operation in line 2. Since \( \ell_p = j \), at the beginning of this while-loop iteration, it follows from the semantics of the \texttt{T.getNode}() operation, that the operation returned the pair \( \langle u, i \rangle \), for some \( i \), where \( h_u = j + 1 \). Now, process \( p \) writes to its local variable \( \ell_p \) only in lines 4 and 5.

\textbf{Case a - } \( p \) writes to \( \ell_p \) in line 4. Then \( p \) increased \( \ell_p \) from \( j \) to \( j + 1 \) in line 4. Then, to prove our claim we need to show that \( p \) owns the node with height \( j + 1 \) on \texttt{path}_p \). Since \( p \) satisfies the if-condition of line 4, it follows from the code structure that \( p \)'s \texttt{u.L.lock}() method in line 3 returned the special value \( \infty \), where \( v_p = u \). Since \( h_u = j + 1 \), and \( p \) successfully captured \texttt{lock u.L} and now owns node \( u \). It also follows that \( p \) has been handed over all nodes on \texttt{path}_p \) with heights in the range \( \{h_u + 1, \ldots, x\} \). Since \( h_u = j \), our claim follows.

\textbf{Case b - } \( p \) writes to \( \ell_p \) in line 5. Let \( \text{val}_p = x \) when \( p \) writes to \( \ell_p \) in line 5. From Part (b), it follows that \( \ell_p \) is increased every time it is written to, and therefore \( \text{val}_p = x > \ell_p \) when \( p \) writes to \( \ell_p \) in line 5. Thus, to prove our claim we need to show that \( p \) owns all nodes on \texttt{path}_p \) with heights in the range \( \{j, \ldots, x\} \). Since \( p \) satisfies the if-condition of line 5 and the \texttt{ALockArray} method \texttt{lock}() only returns a value in \( \{\bot, \infty\} \cup \mathbb{N} \), it follows that \( p \)'s call to \texttt{u.L.lock()} returned a non-\(\{\bot, \infty\} \) value. Thus, \( p \) has captured \texttt{u.L} and now owns node \( u \). It also follows that \( p \) has been handed over all nodes on \texttt{path}_p \) with heights in the range \( \{h_u + 1, \ldots, x\} \). Since \( h_u = j \), our claim follows.

A process is said to attempt to capture node \( u \) if it executes a \texttt{u.L.lock}() method in line 5.

\textbf{Claim E.3.} (a) If two distinct processes \( p \) and \( q \) attempt to capture node \( v \), then their local variables \( i \) have different values.

(b) A node has at most one owner at any point in time.
Proof. We prove our claims for all nodes of height at most \( h \), by induction over integer \( h \).

**Basis** \((h = 1)\) Consider an arbitrary node \( u \) of height 1, such that two distinct processes \( p \) and \( q \) attempt to capture node \( u \). Then processes \( p \) and \( q \) executed a \( \text{getNode}((\text{leaf}_p, 1)) \) and \( \text{getNode}((\text{leaf}_q, 1)) \) in line 2 and received pairs \( \langle u, i \rangle \) and \( \langle u, j \rangle \), and set their local variables \( i_p \) and \( i_q \) to \( i \) and \( j \) respectively. Since \( p \) and \( q \) are distinct, \( \text{leaf}_p \) and \( \text{leaf}_q \) are distinct leaf nodes of tree \( T \), and thus from the semantics of the \( \text{getNode}() \) method it follows that \( i \neq j \), and thus Part (i) follows.

Consider an arbitrary node \( u \) of height 1. From Part (i), it follows that no two processes execute a concurrent call to \( u.L.\text{lock}_i() \) for the same \( i \), and thus it follows from the mutual exclusion property of object \( \text{ALockArray}_\Delta \), that at most one process captures \( u.L \). By definition, a process can become an owner of node \( u \) only if it captures \( u.L \) or if it is handed over node \( u \) from some other process \( q \). If a node \( u \) is handed over from some other process \( q \), then \( q \) also ceases to be the owner of node \( u \) at that point, and thus the number of owners of \( u \) does not increase upon a hand over. Thus it follows that node \( u \) has at most one owner at any point in time, and thus Part (ii) follows.

**Induction Step** \((h > 1)\) Consider an arbitrary node \( u \) of height \( h \), such that two distinct processes \( p \) and \( q \) attempt to capture node \( u \). Then processes \( p \) and \( q \) executed a \( \text{getNode}((\text{leaf}_p, h)) \) and \( \text{getNode}((\text{leaf}_q, h)) \) in line 2 and received pairs \( \langle u, i \rangle \) and \( \langle u, j \rangle \), and set their local variables \( i_p \) and \( i_q \) to \( i \) and \( j \) respectively. For the purpose of a contradiction, assume \( i = j \). From the semantics of \( \text{getNode}() \) method, \( i = j \) only if the \((h-1)\)-th nodes on \( \text{path}_p \) and \( \text{path}_q \) are the same (say \( w \)). From the induction hypothesis of Part (i) for \( h - 1 \), \( w \) has at most one owner at any point in time. Since \( \ell_p = \ell_q = h - 1 \) when \( p \) and \( q \) attempt to capture node \( u \), it follows from Claim (L.2), that \( p \) and \( q \) own all nodes up to height \( h - 1 \) on their individual paths \( \text{path}_p \) and \( \text{path}_q \). Then \( p \) and \( q \) are both the owners of \( w \) – a contradiction. Thus, Part (ii) follows.

Since Part (ii) holds for \( h \), Part (iii) holds for \( h \), as argued in the **Basis** case. \( \square \)

**Lemma E.4.** The mutual exclusion property is satisfied during history \( H \).

**Proof.** Assume two processes \( p \) and \( q \) are in their Critical Section at the same time, i.e., both processes returned a non-L value from their last \( \text{lock}() \) call. Then both processes executed line 11 and thus \( \ell_p = \ell_q = T.\text{height} \) holds. Then from Claim (L.2) it follows that both \( p \) and \( q \) own node \( T.\text{root} \). But from Claim (E.3), at most one process may own \( T.\text{root} \) at any point in time – a contradiction. \( \square \)

**Claim E.5.** Process \( p \) repeats the while-loop in \( \text{lock}() \) at most \( \Delta \) times.

**Proof.** Consider an arbitrary process \( p \) that calls \( \text{lock}() \). From the code structure of \( \text{lock}() \), it follows that if \( p \) repeats an iteration of the while-loop then \( p \) either executed line 4 or line 5 in its previous iteration. Then it follows from Claim (L.2) that \( p \) increases \( \ell_p \) every time it repeats an iteration of the while-loop. Since the height of the \( T \) is \( \Delta \), our claim follows. \( \square \)

**Lemma E.6.** No process starves in history \( H \).

**Proof.** Since no two processes execute a concurrent call to \( u.L.\text{lock}_i() \) for the same \( i \) (from Claim (L.3)), it follows from the starvation-freedom property of object \( \text{ALockArray}_\Delta \), that a process does not starve during a call to \( u.L.\text{lock}() \) for some node \( u \) on its path.

Consider an arbitrary process \( p \) that calls \( \text{lock}() \). Since \( p \) repeats the while-loop in \( \text{lock}() \) at most \( \Delta \) times before returning from line 11 (follows from Claim (L.5)), it follows that \( p \) starves only if \( p \) starves during a call to \( u.L.\text{lock}() \) in line 3 for some node \( u \). As already argued, this cannot happen, and thus our claim follows. \( \square \)
Lemma E.7. Process \( p \) incurs \( O(\Delta) \) RMRs during \( \text{release}_p() \).

Proof. Consider \( p \)'s call to \( \text{release}() \). Since \( \ell_p \leq T.\text{height} = \Delta \), it follows from an inspection of the code that during \( \text{release}() \), \( p \) executes at most \( \Delta \) calls to \( \text{L.release}() \) (in line 14), and at most one of the \( \text{L.release}() \) calls returns \text{true}. As per the properties of object \text{ALockArray}\( \Delta \) (Lemma 3.1), a process incurs \( O(\Delta) \) RMRs during a call to \( \text{L.release}() \), if the call returns \text{true}, otherwise \( O(1) \) RMRs. Then our claim follows immediately. \( \square \)

Lemma E.8. Process \( p \) incurs \( O(\Delta) \) RMRs in expectation during \( \text{lock}_p() \).

Proof. A process may or may not receive a signal to abort during \( \text{lock}_p() \). Case a - \( p \) does not receive a signal to abort during \( \text{lock}_p() \). As per the properties of object \text{ALockArray}\( \Delta \) (Lemma 3.1), if a process does not receive a signal to abort during a call to \( \text{L.lock}() \), then the process incurs \( O(1) \) RMRs in expectation during the call. Since \( p \) repeats the while-loop in \( \text{lock}() \) at most \( \Delta \) times (by Claim E.5), and \( p \) does not receive a signal to abort during \( \text{lock}_p() \), it follows that \( p \) incurs \( O(\Delta) \) RMRs in expectation during \( \text{lock}_p() \).

Case b - \( p \) receives a signal to abort during \( \text{lock}_p() \). As per the properties of object \text{ALockArray}\( \Delta \) (Theorem 3.1), if a process aborts during a call to \( \text{L.lock}() \), then the process incurs \( O(\Delta) \) RMRs in expectation during the call. Since \( p \) repeats the while-loop in \( \text{lock}() \) at most \( \Delta \) times (by Claim E.5), and \( p \) executes at most one call to \( \text{u.L.lock}() \) after having received an abort signal, it follows that \( p \) incurs \( O(\Delta) \) RMRs in expectation during \( \text{lock}_p() \). \( \square \)

Lemma E.9. Method \( \text{release}() \) is wait-free.

Proof. As per the bounded exit property of object \text{ALockArray}\( \Delta \), method \( \text{release}() \) of the object is wait-free. Then our claim follows immediately from an inspection of the code of \( \text{release}() \). \( \square \)

Lemma E.10. The abort-way is wait-free and has \( O(\Delta) \) RMR complexity.

Proof. The abort-way of a process \( p \) consists of the steps executed by the process after receiving a signal to abort and before completing its passage. From Lemma E.9 and E.7 method \( \text{release}_p() \) is wait-free, and has \( O(\Delta) \) RMR complexity. From Claim E.5, a process repeats the while-loop in \( \text{lock}_p() \) at most \( \Delta \) times. Then from an inspection of the code it follows that a process executes all steps during its passage in a wait-free manner, except the call to \( \text{u.L.lock}() \) in line 8 and that a process incurs at most \( O(\Delta) \) RMRs during all these steps.

To complete our proof we now show that if a process has received a signal to abort and it executes a call to \( \text{u.L.lock}() \) in line 8 for some node \( u \), then the process executes \( \text{u.L.lock}() \) in a wait-free manner and incurs \( O(\Delta) \) RMR during the call, and does not call \( \text{v.L.lock}() \) for any other node \( v \).

Suppose that \( p \) has received a signal to abort, and \( p \) executes a call to \( \text{u.L.lock}() \) call in line 8. Since \( p \) has received a signal to abort, it follows that \( p \) executes the abort-way of the node lock \( u.L \). As per the properties of object \text{ALockArray}\( \Delta \) (Lemma 3.1), its abort-way is wait-free and has \( O(\Delta) \) RMR complexity. Then \( p \) executes the \( \text{u.L.lock}() \) call in line 8 in a wait-free manner and incurs \( O(\Delta) \) RMR complexity. It then goes on to satisfy the if-condition of line 6 and executes a call to \( \text{release}() \) in line 7 and returns \( \perp \) in line 8 thereby completing its abort-way. Thus, our claim holds. \( \square \)

Theorem 1.1 follows from Lemmas E.4, E.6, E.7, E.8, E.9 and E.10.
F Remaining Proofs of Properties of $\text{ALockArray}_n$

Claim F.1. Suppose a process $p$ executes a call to $\text{lock}_p()$ during a passage. The value of $\text{Role}[p]$ at various times is as follows.

<table>
<thead>
<tr>
<th>Points in time</th>
<th>Value of $\text{Role}[p]$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$t^0_p$</td>
<td>${\infty, \text{KING}, \text{QUEEN}, \text{PAWN}}$</td>
</tr>
<tr>
<td>$[t^1_p, t^2_p)$</td>
<td>PAWN</td>
</tr>
<tr>
<td>$t^3_p$</td>
<td>$\text{PAWN}_P$</td>
</tr>
<tr>
<td>$[t^4_p, t^5_p)$</td>
<td>${\text{KING}, \text{QUEEN}, \text{PAWN}_P}$</td>
</tr>
<tr>
<td>$t^6_p$</td>
<td>QUEEN</td>
</tr>
<tr>
<td>$[t^7_p, t^8_p)$</td>
<td>${\text{KING}, \text{QUEEN}, \text{PAWN}_P}$</td>
</tr>
</tbody>
</table>

Proof. Since the values returned by a $\text{Ctr.inc()}$ operation are in $\{\infty, 0, 1, 2\} = \{\infty, \text{KING}, \text{QUEEN}, \text{PAWN}\}$, $\text{Role}[p]$ is set to one of these values in line 5. Hence, $\text{Role}[p] \in \{\infty, \text{KING}, \text{QUEEN}, \text{PAWN}\}$ at $t^5_p$. If $p$ satisfies the if-condition of line 6 then $\text{Role}[p] = \text{PAWN}$, and $p$ changes $\text{Role}[p]$ next only in line 9. Hence, $\text{Role}[p] = \text{PAWN}$ during $[t^7_p, t^8_p)$. In line 9 $p$ changes $\text{Role}[p]$ to $\text{PAWN}_P$ and does not change $\text{Role}[p]$ thereafter. Hence, $\text{Role}[p] = \text{PAWN}_P$ at $t^9_p$.

Process $p$ does not change $\text{Role}[p]$ after line 9. To break out of the getLock loop, $\text{Role}[p] \in \{\text{KING}, \text{QUEEN}, \text{PAWN}_P\}$ must be satisfied when $p$ executes line 12. Hence, $\text{Role}[p] = \{\text{KING}, \text{QUEEN}, \text{PAWN}_P\}$ during $[t^13_p, t^14_p)$. Since $p$ executes line 13 only after breaking out of the getLock loop, $\text{Role}[p] \in \{\text{KING}, \text{QUEEN}, \text{PAWN}_P\}$ at $t^13_p$. If $p$ satisfies the if-condition of line 13 then $\text{Role}[p] = \text{QUEEN}$, and since $p$ does not change $\text{Role}[p]$ thereafter, $\text{Role}[p] = \text{QUEEN}$ at $t^14_p$. $\square$

Claim F.2. Suppose a process $p$ executes a call to $\text{abort}_p()$. The value of $\text{Role}[p]$ at various points in time is as follows.

<table>
<thead>
<tr>
<th>Points in time</th>
<th>Value of $\text{Role}[p]$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$[t^1_p, t^2_p)$</td>
<td>${\text{QUEEN}, \text{PAWN}}$</td>
</tr>
<tr>
<td>$t^3_p$</td>
<td>PAWN</td>
</tr>
<tr>
<td>$[t^4_p, t^5_p)$</td>
<td>$\text{PAWN}_P$</td>
</tr>
<tr>
<td>$t^6_p$</td>
<td>QUEEN</td>
</tr>
</tbody>
</table>

Proof. Process $p$ calls $\text{abort}_p()$ only if $p$ has received a signal to abort and $p$ is busy waiting in one of lines 2, 7, or 14. Then, the last line executed by $p$ before calling $\text{abort}_p()$ is line 2, 7, or 14. From Claim F.1 it follows that $\text{Role}[p] = \text{PAWN}$ at $t^7_p$, and $\text{Role}[p] = \text{QUEEN}$ at $t^14_p$.

Now, $p$’s local variable $\text{flag}$ is set to value $\text{true}$ for the first time in line 8. If $p$ fails the if-condition of line 8 then $p$ must have executed line 8 and thus $p$ broke out of the busy-wait loop of line 2. Then, $p$ last executed line 7 or line 14 before calling $\text{abort}_p()$. Hence, $\text{Role}[p] \in \{\text{PAWN}, \text{QUEEN}\}$ in $[t^19_p, t^20_p)$, since $p$ changes $\text{Role}[p]$ next only in line 22.

If $p$ satisfies the if-condition of line 20 then $\text{Role}[p] = \text{PAWN}$, and $p$ changes $\text{Role}[p]$ next only in line 22. Hence, $\text{Role}[p] = \text{PAWN}$ at $t^21_p$. In line 22 $p$ changes $\text{Role}[p]$ to $\text{PAWN}_P$ and $p$ does not change $\text{Role}[p]$ after that. Hence, $\text{Role}[p] = \text{PAWN}_P$ during $[t^22_p, t^23_p)$. If $p$ does not satisfy the if-condition of line 20 then $\text{Role}[p] = \text{QUEEN}$ at $[t^26_p, t^30_p)$ follows. $\square$

Claim F.3. Suppose a process $p$ executes a call to $\text{release}_p(j)$ during a passage. The value of $\text{Role}[p]$ at various points in time is as follows.

64
Proof. Suppose the point in time $t_p^{41}$. Then, $p$ is executing a call to $\text{release}_p(j)$, and $p$ last executed a call to $\text{lock}_p()$ that returned a non-$\bot$ value. Then, $p$’s call to $\text{lock}_p()$ either returned from line 17 in $\text{lock}_p()$ or from line 23 or line 27 in $\text{abort}_p()$. From Claim F.4, $\text{Role}[p] \in \{\text{KING, QUEEN, PAWN}_p\}$ at time $t_p^{17}$ and from Claim F.2, $\text{Role}[p] = \text{PAWN}_p$ at $t_p^{23}$ and $\text{Role}[p] = \text{QUEEN}$ at $t_p^{27}$. Therefore, $\text{Role}[p] \in \{\text{KING, QUEEN, PAWN}_p\}$ at time $t_p^{41}$.

From Claim F.4, $\text{Role}[p]$ is unchanged during $\text{release}_p()$. Therefore, $\text{Role}[p] \in \{\text{KING, QUEEN, PAWN}_p\}$ during $[t_p^{41} \cdot t_p^{43}]$ and $[t_p^{43} \cdot t_p^{45}]$. Then, from the if-conditions of lines 35 and 43, it follows immediately that $\text{Role}[p] = \text{KING}$ at $t_p^{43}$, and $\text{Role}[p] = \text{QUEEN}$ at $t_p^{43}$, and $\text{Role}[p] = \text{PAWN}_p$ at $t_p^{46}$.

\[\square\]

Claim F.4. Suppose a process $p$ executes a call to $\text{doCollect}_p()$, $\text{helpRelease}_p()$ or $\text{doPromote}_p()$ during a passage. The value of $\text{Role}[p]$ at various points in time is as follows.

<table>
<thead>
<tr>
<th>Points in time</th>
<th>Value of $\text{Role}[p]$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$[t_p^{41}, t_p^{43}]$</td>
<td>${\text{KING, QUEEN, PAWN}_p}$</td>
</tr>
<tr>
<td>$[t_p^{43}, t_p^{45}]$</td>
<td>${\text{KING, QUEEN}}$</td>
</tr>
<tr>
<td>$[t_p^{45}, t_p^{49}]$</td>
<td>${\text{KING, QUEEN, PAWN}_p}$</td>
</tr>
</tbody>
</table>

Proof. From the code structure, $p$ does not change $\text{Role}[p]$ during $\text{doPromote}()$, $\text{doCollect}_p()$ and $\text{helpRelease}()$.

From a code inspection, $\text{doCollect}_p()$ is called by $p$ only in lines 29 and 58. From Claim F.2, $\text{Role}[p] = \text{QUEEN}$ at $t_p^{29}$ and from Claim F.3, $\text{Role}[p] = \text{KING}$ at $t_p^{58}$. Since $\text{Role}[p]$ is unchanged during $\text{doCollect}_p()$, it follows that $\text{Role}[p] \in \{\text{KING, QUEEN}\}$ during $[t_p^{29} \cdot t_p^{58}]$.

Now, suppose $p$ executes a call $\text{helpRelease}_p()$. From a code inspection, $\text{helpRelease}_p()$ is called by $p$ only in lines 50, 59, and 43. From Claim F.2, $\text{Role}[p] = \text{QUEEN}$ at $t_p^{50}$ and from Claim F.3, $\text{Role}[p] = \text{KING}$ at $t_p^{59}$ and $\text{Role}[p] = \text{QUEEN}$ at $t_p^{43}$. Since $\text{Role}[p]$ is unchanged during $\text{helpRelease}()$, it follows that $\text{Role}[p] \in \{\text{KING, QUEEN}\}$ during $[t_p^{50} \cdot t_p^{43}]$.

Now, suppose $p$ executes a call $\text{doPromote}_p()$. From a code inspection, $\text{doPromote}_p()$ is called by $p$ only in lines 46 and 62. From Claim F.3, $\text{Role}[p] = \text{PAWN}_p$ at $t_p^{46}$ and from earlier in this claim, $\text{Role}[p] \in \{\text{KING, QUEEN}\}$ at $t_p^{46}$. Since $\text{Role}[p]$ is unchanged during $\text{doPromote}()$, it follows that $\text{Role}[p] \in \{\text{KING, QUEEN, PAWN}_p\}$ during $[t_p^{50} \cdot t_p^{46}]$. \[\square\]
